I. Abstract

A. Brief introduction

The literature on sparse precision matrix estimation is rapidly growing and receiving significant attention from the research community [4], [3]. Many strong methods are valid only for Gaussian variables [8], [7]. One of the most commonly used approaches in this case is glasso [6] which aims to minimize the negative L1-penalized log-likelihood function:

$$\min_{\Theta>0} tr(\Theta S) - \log \det(\Theta) + \rho \|\Theta\|_1$$  \hspace{1cm} (1)

$$S = \frac{1}{n} \sum_{i=1}^{n} (x_i - \mu)(x_i - \mu)^T$$ is the sample covariance matrix of observed independent samples $x_1, \ldots, x_n$ from $N(\mu, \Sigma)$. $\Theta = \Sigma^{-1}$ is the precision matrix, $\rho$ is a regularization parameter.

In practice, data may deviate from normality in various ways, outliers and heavy tails frequently occur that can severely degrade the Gaussian models performance. A natural solution is to turn to heavier tailed distributions that remain tractable. For this purpose, we propose a penalized version of EM-algorithm for Gaussian Scale Mixtures. The proposition we state below allows us to design the penalized EM algorithm valid for the distributions that can be seen as Gaussian Scale Mixtures.

Definition 1 (Scale mixture of multivariate Gaussian distributions). If $\mu$ is a $p$-dimensional vector, $\Sigma$ is a $p \times p$ positive definite symmetric matrix and $f_W$ is a probability distribution function of a univariate positive variable $W \in \mathbb{R}^+$, then the $p$-dimensional density given by

$$p(x; \mu, \Sigma, \Theta) = \int_0^\infty \mathcal{N}_p(x; \mu, \Sigma w) f_W(w; \Theta) dw$$  \hspace{1cm} (2)

is said to be a scale mixture of Gaussian densities with mixing distribution function $f_W$. If vector $X$ has density (2), we write $X \sim GSM_p(\mu, \Sigma, f_W)$ and we refer to $W$ as the mixing variable.

Proposition 1. Let $X \sim GSM_p(\mu, \Sigma, f_W)$ and $W$ denote the mixing variable. Then $X$ has an elliptical distribution

$$p(x; \mu, \Sigma, f_W) = (2\pi)^{\frac{p}{2}} |\Sigma|^{-\frac{1}{2}} g((x - \mu)^T \Sigma^{-1}(x - \mu))$$

with generator $g(t) = g(t) = \int_0^\infty w^{\frac{p}{2}} \exp(-\frac{1}{2}tw) f_W(w) dw$. It follows that

$$E[W|x, \Psi] = -2 \frac{g'((x - \mu)^T \Sigma^{-1}(x - \mu))}{g((x - \mu)^T \Sigma^{-1}(x - \mu))},$$

where $g'$ is the derivative of $g$.

B. Penalized EM algorithm for Gaussian Scale Mixtures

Like in the Gaussian case, we put a L1-norm penalty on the elements of the matrix $\Theta$ and wish to maximize the penalized log-likelihood function. Let us consider $n$ i.i.d. variables $x_i$, following a $GSM_p(\mu, \Sigma, f_W)$ distribution for $i = 1 : n$, the model parameters to estimate are $\Psi = \{\mu, \Sigma, \Theta\}$. Introducing the corresponding latent variables $\{W_i, i = 1:n\}$, we can consider an EM algorithm. The expected complete likelihood $Q(\Psi, \Psi^{(r-1)})$ at iteration $(r)$ of the algorithm takes the form:

$$Q(\Psi, \Psi^{(r-1)}) = \sum_{i=1}^{n} \left[ \log p(x_i|W_i; \mu, \Sigma)|x_i, \Psi^{(r-1)} \right] +$$

$$+ \left[ \log f_W(W_i|x_i, \Psi^{(r-1)}) \right] - \rho \|\Sigma^{-1}\|_1 \hspace{1cm} (3)$$

By definition the distribution of $(x_i|W_i = w_i) = N(\mu, \Sigma)$ and does not depend on $\Theta$.

The E-step is the same as for non-penalized version. For $i = 1 : n$, compute $E[W_i|x_i, \Psi^{(r-1)}]$ according to Proposition 1 we get:

$$E[W_i|x_i, \Psi^{(r-1)}] = \bar{w}_i^{(r)} = -2 \frac{g((x_i - \mu)^T \Sigma^{(r-1)}(x_i - \mu))}{g((x_i - \mu)^T \Sigma^{(r-1)}(x_i - \mu))},$$

Figure 1. For Gaussian data, the $t$CLIME and EPIC performance is found by solving the following optimization problem:

$$\min_{\Theta>0} tr(\Theta S) - \log \det(\Theta) + \rho \|\Theta\|_1.$$

where a “weighted sample covariance matrix” $S^{(r)}$ and vector $\mu$ are computed as $S^{(r)} = \frac{1}{n} \sum_{i=1}^{n} \bar{w}_i^{(r)} (x_i - \mu^{(r)})(x_i - \mu^{(r)})^T$ and $\mu^{(r)} = \frac{1}{n} \sum_{i=1}^{n} \bar{w}_i^{(r)} x_i$. Note that (4) is a similar objective function minimized by glasso, so that the proposed penalized algorithm reduces to solving at each iteration a glasso optimization problem. There is no need to inverse the matrix $\Sigma$ on each step since for all $i = 1 : n$ the variables $\bar{w}_i^{(r)}$ depend on $\Theta^{(r-1)}$ and not on $\Sigma^{(r-1)}$. Moreover, it is shown in [1] that the optimization problem 4 can be replaced by more efficient CLIME algorithm [2].

C. Results

As a particular example of the described approach, Finegold and Drton [5] proposed a $t$lasso procedure for multivariate t-distribution. We compare the results of $t$lasso, CLIME [1] which a modified version of $t$lasso, CLIME [3] and EPIC method [9] designed for elliptical distributions. To measure how well the sparsity of the true precision matrix is recovered, we plot ROC curves presented in Figure 1. For Gaussian data, the $t$CLIME and EPIC performance is similar and better than that of $t$lasso and CLIME. When data is generated from a t-distribution, tCLIME significantly outperforms CLIME and also shows better results than EPIC and $t$lasso.

Fig. 1: ROC curves illustrating the performance of \textit{tlasso}, CLIME, tCLIME and EPIC methods on 2 different data sets. A random $100 \times 100$ sparse precision matrix $\Theta$ is generated according to the procedure described in [5]; $n=150$ observations are simulated from $t_{100}(0, \Theta^{-1}, 3)$ and $N_{100}(0, \Theta^{-1})$. The four algorithms are then run with different values of $\rho$ and the whole process is repeated 50 times. The tuning parameter $\rho$ is chosen in the range $[0, 1.25]$ with stepsize 0.05 for \textit{tlasso} and $[0.01, 0.4]$ with stepsize 0.01 for CLIME, tCLIME anf EPIC.
