ABSTRACT

The chemical bath deposition of nanowires is of high interest for a wide variety of optoelectronic, piezoelectric, and sensing devices, but a theoretical description of the elongation process is still missing despite its critical importance. By solving Fick's diffusion equations in combination with thermodynamic computations, we determine the expression of the axial growth rate of nanowires and its temporal dependence under dynamic conditions, namely in a sealed reactor where the depletion of chemical reactants occurs. The theoretical model is found to be in very good agreement with a large set of experimental data specifically collected in the case of the chemical bath deposition of ZnO nanowires. In particular, an activation energy of 198 ± 24 kJ/mol is deduced for the elongation process of ZnO nanowires, involving the energy barriers for both the dehydration process of Zn(II) species (*i.e.* $[\text{Zn}(\text{H}_2\text{O})_6]^{2+}$ ions) and their subsequent direct incorporation onto the *c*-plane top faces. This shows its high potential for deeply investigating the physicochemical processes at work in the chemical bath. By using the theoretical model as a predictive approach, a complete growth diagram reporting the evolution of the length of ZnO nanowires vs effective growth time and temperature is also gained over a broad range of conditions, revealing its additional high potential for applied research and industrial purposes. The present general approach is further compatible with a broad range of chemicals in solution and of semiconducting materials grown by chemical bath deposition.

1. INTRODUCTION

As a low-cost, low-temperature, and easily implemented process, chemical bath deposition (CBD) is of great interest to form nanostructures with a dedicated structural morphology.^{1,2} It is further compatible with a variety of applications in the fields of optoelectronics,³⁻⁵ piezoelectricity,^{6,7} and sensing,⁸ and it can be scaled up for industrial purposes.⁹ One of the most-well known use of CBD over the last decade has been devoted to the formation of ZnO nanostructures, mainly nanowires (NWs), using the spontaneous and selective area growths on a variety of flexible and rigid substrates.¹⁰⁻¹⁴ A reactor containing the bath comprising the chemical precursors composed of a zinc salt and an ammine mixed in aqueous solution is typically sealed and placed in an oven heated at a temperature in the range of 60-90 °C.¹⁵⁻¹⁸ The CBD process induces the heterogeneous formation of ZnO NWs that is achieved on a dedicated nucleation surface, *e.g.* a ZnO polycrystalline seed layer¹⁹⁻²¹ or single crystal,^{22,23} or a metallic seed layer.²⁴⁻²⁶ In the most widely used case of a sealed reactor,^{11,16,18,25,26} the system is thus closed with no continuous addition of chemical precursors during the CBD process, which corresponds to dynamic conditions. The axial growth rate of ZnO NWs is thus basically not constant over time and decreases as their elongation proceeds owing to the depletion of the chemical bath in reactants, typically the Zn(II) ions as the limiting species. As a result, the elongation of ZnO NWs and specifically its temporal dependence has emerged as a critical issue both for fundamental research purposes aiming at more deeply understanding the physicochemical processes at work as well as for applied research and industrial purposes targeting the massive production of ZnO NWs.

However, despite its primary importance, the theoretical modeling of the elongation process of ZnO NWs by CBD through the expression of its axial growth rate has so far been limited to static conditions,²⁷⁻²⁹ namely in a continuous flow reactor. No temporal dependence has been reported to take into account dynamic conditions in a sealed reactor originating from the depletion of the chemical bath in reactants. Boercker *et al.* showed that the length of ZnO NWs is inversely proportional to its surface density in a growth regime limited by the diffusive transport of chemical reactants.²⁷ Later on, Cheng *et al.* established a comprehensive analysis of the surface reaction-/diffusive transport-limited growth regimes to get the expression of the axial growth rate under homeostatic conditions.²⁸ They developed a continuous flow reactor maintaining homeostatic chemical precursor concentrations and constant growth temperature to successfully investigate the elongation process of ZnO NWs. Cossuet *et al.*

subsequently reported that Zn-polar ZnO nanorods have a higher growth rate than O-polar ZnO nanorods owing to their larger surface reaction rate constant by using the same analysis as in Ref. ^{28,29} In the present case, the reactor was sealed and thus the system was closed, but the active surface area for the selective area growth of ZnO nanorods on patterned ZnO single crystals was very small as compared to the sample size and solution volume, somehow corresponding to static conditions.

In this article, we establish and develop a theoretical model of the axial growth rate of ZnO NWs by CBD and of its temporal dependence under dynamic conditions in the framework of the surface reaction-/diffusive transport-limited growth regime analysis in combination with thermodynamic computations. The theoretical modeling is applied to the elongation process of ZnO NWs when grown in a broad range of CBD conditions in order to reveal the physicochemical processes at work on their *c*-plane top faces. These findings further reporting a predictive approach of the CBD process under dynamic conditions are of high and broad interest for a wide variety of chemicals in solution and of semiconducting materials in the framework of NW growth.

2. EXPERIMENTAL SECTION

2.1. Seed layer deposition. The 2 x 2 cm² samples were prepared from Si (100) substrates cleaned with acetone and isopropyl alcohol in an ultrasonic bath. In order to perform the ZnO seed layer deposition, a solution containing 375 mM of zinc acetate dihydrate (Zn(CH₃COO)₂·2H₂O, Sigma-Aldrich) and 375 mM of monoethanolamine (MEA, Sigma-Aldrich) in pure ethanol was prepared and stirred for several hours at 60 °C on a hot plate and then at room temperature. The substrates were subsequently dipped in the solution under a controlled atmosphere (< 15 % hygrometry) and annealed for 10 min at 300 °C to evaporate residual organic compounds and for 1 h at 500 °C to crystallize the ZnO seed layer.

2.2. Synthesis of ZnO NWs. ZnO NWs were then grown by CBD with a chemical bath containing an aqueous solution of zinc nitrate hexahydrate (Zn(NO₃)₂·6H₂O, Sigma-Aldrich) and hexamethylenetetramine (HMTA, Sigma-Aldrich) mixed in an equimolar ratio of 30 mM (pH = 6.9). To increase the pH to 11.0, 800 mM of ammonia (NH₃, Sigma-Aldrich) was further added to the chemical bath. The samples were placed face down in a sealed reactor containing the precursor solution and heated in a regular oven at 80 – 95 °C in the range of 40 min to 8 h.

2.3. Morphological characterization. The morphological properties of ZnO NWs were investigated with a FEI Quanta 250 field-emission scanning electron microscope (FESEM). By using ImageJ software, the *c*-plane surface area ratios of ZnO NWs were assessed from top-view FESEM images, in which a filter was applied to only display their *c*-plane top facets. Moreover, the mean lengths of ZnO NWs were measured from cross-sectional view FESEM images. The numerical values are summarized in **Table S1**.

2.4. Thermodynamic simulations. Thermodynamic simulations were performed using Visual MINTEQ software for determining the equilibrium concentration of Zn(II) ions as a function of the growth temperature and NH₃ concentration.^{15,49} Zn²⁺ ion was considered as a single metallic cation, which is able to form complexes with two possible ligands, namely NH₃ and HO⁻, denoted as L, by following the general reaction: $n\text{Zn}^{2+} + i\text{L} \leftrightarrow \text{Zn}_n\text{L}_i^{2n+}$ where $\text{Zn}_n\text{L}_i^{2n+}$ is the complex considered and i the coordination number. The global thermodynamic equilibrium is calculated from the stability constants $\beta_i^L = \frac{[\text{Zn}_n\text{L}_i^{2n+}]}{[\text{Zn}^{2+}]^n[\text{L}]^i}$ associated with each chemical reaction, whose the typical values were taken from NIST database.

3. RESULTS AND DISCUSSION

3.1. Description of the theoretical model under dynamic conditions. We consider a semi-infinite reactor – as defined for $z > 0$ – where an infinite substrate is placed at $z = 0$ as seen in **Figure 1**. In order to establish the expression of the length of ZnO NWs and its temporal dependence, namely their elongation under dynamic conditions where the depletion of chemical reactants occurs, we apply Fick's second diffusion equation in one dimension as follows:³⁰

$$\frac{\partial C}{\partial t} = D \frac{\partial^2 C}{\partial z^2} \quad (\text{Eq.1})$$

with the three following boundary conditions:

$$C(z, t = 0) = C_0 \quad (\text{Eq.2})$$

$$C(z = \infty, t) = C_0 \quad (\text{Eq.3})$$

$$\frac{dC(z = 0, t)}{dz} = \frac{k_1 S}{D} (C(z = 0, t) - C_{eq}) \quad (\text{Eq.4})$$

where $C(z, t)$ is the concentration of Zn(II) ions (m^{-3}) at a height z above the substrate and at a growth time t , C_{eq} is the equilibrium concentration of Zn(II) ions (m^{-3}), k_1 is the first order reaction rate constant of ZnO crystallization

(m.s⁻¹), S is the c -plane top surface area ratio and D is the diffusion coefficient of Zn(II) ions in aqueous solution at the temperature T (m².s⁻¹).

Eqs.2 and 3 report that C_0 corresponds to the concentration of Zn(II) ions at $t = 0$ wherever in the chemical bath and is assumed to match the concentration of Zn(II) ions located infinitely far from the substrate at any t . Eq.4 accounts for the consumption of the limiting reactants (*i.e.* Zn(II) ions) on the growth front located at the c -plane top facet of ZnO NWs. It is obtained by applying Fick's first diffusion equation at $z = 0$ by further neglecting the development of the growth front with time as well as by considering S as a constant parameter in a first approximation.

In order to solve this second-order partial differential equation, we apply the Laplace transform to Eq.1, and, by using Eq.2, we obtain:

$$\frac{\partial^2 c}{\partial z^2} - \frac{p}{D} c = \frac{-C_0}{D} \quad (\text{Eq.5})$$

where $c(z, p)$ is the Laplace transform of $C(z, t)$. The temporal derivative is thus removed and we get an ordinary differential equation. By solving Eq.5 with Eqs.3 and 4, we obtain:

$$c(z, p) = \frac{C_0}{p} - \frac{\frac{k_1 S}{D} (C_0 - C_{eq})}{p \left(\sqrt{\frac{p}{D}} + \frac{k_1 S}{D} \right)} \exp \left(-\sqrt{\frac{p}{D}} z \right) \quad (\text{Eq.6})$$

By applying the inverse Laplace transform to Eq.6, we get the following expression:

$$C(z, t) = (C_0 - C_{eq}) \left[\operatorname{erf} \left(\frac{z}{2\sqrt{Dt}} \right) + \exp \left(\frac{k_1 S}{D} z + \frac{(k_1 S)^2}{D} t \right) \operatorname{erfc} \left(\frac{z}{2\sqrt{Dt}} + \frac{k_1 S}{\sqrt{D}} \sqrt{t} \right) \right] + C_{eq} \quad (\text{Eq.7})$$

In order to deduce the time-dependent axial growth rate of ZnO NWs denoted as $R_c(t)$, we consider the relation:

$$R_c(t) = \frac{k_1}{\rho} (C(z = 0, t) - C_{eq}) \quad (\text{Eq.8})$$

where ρ is the atomic density of wurtzite ZnO that is equal to $4.20 \times 10^{28} \text{ m}^{-3}$. This directly gives:

$$R_c(t) = \frac{(C_0 - C_{eq}) k_1}{\rho} \left[\exp \left(\frac{(k_1 S)^2}{D} t \right) \operatorname{erfc} \left(\frac{k_1 S}{\sqrt{D}} \sqrt{t} \right) \right] \quad (\text{Eq.9})$$

The length of ZnO NWs denoted as L and its temporal dependence is, in turn, deduced by integrating Eq.9, which yields:

$$L(t) = \frac{(C_0 - C_{eq})D}{\rho k_1 S^2} \left[\exp\left(\frac{(k_1 S)^2}{D} t\right) \operatorname{erfc}\left(\frac{k_1 S}{\sqrt{D}} \sqrt{t}\right) + 2k_1 S \sqrt{\frac{t}{D\pi}} - 1 \right] \quad (\text{Eq.10})$$

In the following, we define ΔC as $C_0 - C_{eq}$, which represents the effective concentration involved in the elongation process of ZnO NWs. A more detailed proof to get Eq.10 is available in Supporting Information.

As a direct comparison, we also consider the axial growth rate of ZnO NWs under static conditions denoted as R_c^{static} as given in Refs. ^{27–29} by:

$$L(t) = R_c^{static} t = \frac{k_1 C_0 D}{\rho D + \rho \delta k_1 S} t \quad (\text{Eq.11})$$

where δ is the stagnant layer thickness (m), *i.e.* the thickness of fluid above the ZnO NWs subjected to the diffusive transport of Zn(II) ions.

Figure 1. Schematic of the geometry used to establish the theoretical model of the axial growth rate of ZnO NWs by CBD and its temporal dependence under dynamic conditions (*i.e.* considering the depletion of chemical reactants).

Under dynamic conditions where the depletion of chemical reactants is considered (*i.e.*, using a sealed reactor), we deduce from Eq.9 that the axial growth rate of ZnO NWs decreases by increasing the growth time, which implies, from Eq.10, that their elongation nonlinearly increases. In contrast, under static conditions where no depletion of chemical reactants is taken into account (*i.e.*, using a continuous flow reactor), the axial growth rate of ZnO NWs is constant and Eq.11 clearly reveals that their elongation linearly increases. This nonlinearity has thus not been considered in the previous theoretical model under static conditions as reported in Refs. ^{27–29}, although it has been revealed by typical experimental data reporting the evolution of the length of ZnO NWs with growth time under dynamic conditions.^{31–33}

Additionally, the equilibrium concentration of Zn(II) ions denoted as C_{eq} , for which its value depends on the CBD conditions, was assessed for a given set of growth parameters through dedicated thermodynamic calculations by using Visual MINTEQ software. The evolution of C_{eq} as a function of the NH_3 concentration (*i.e.* of the pH) at different temperatures is presented in **Figure 2** for a chemical bath containing an equimolar concentration C_0 of $\text{Zn}(\text{NO}_3)_2$ and HMTA of 30 mM. We see that C_{eq} is strongly dependent upon the NH_3 concentration, and hence cannot be neglected in most cases. In particular, for a NH_3 concentration of 30 mM corresponding in a first approximation to what is typically provided by the hydrolysis of HMTA, C_{eq} is as high as 15.2 mM, dividing by more than a half the available concentration of Zn(II) species for the elongation of ZnO NWs. Two growth regimes can further be identified: i) below a NH_3 concentration of 60 mM, C_{eq} does not depend on the growth temperature and the remaining Zn(II) species are mainly in the form of Zn^{2+} ions, ii) above a NH_3 concentration of 250 mM, C_{eq} depends on the growth temperature and the remaining Zn(II) species are mostly in the form of $\text{Zn}(\text{NH}_3)_4^{2+}$ ions. When the NH_3 concentration lies in the range of 60 – 250 mM, C_{eq} is negligible, reflecting very high supersaturation levels. However, these CBD conditions are known to be experimentally unfavorable for the heterogeneous formation of ZnO NWs onto the substrate, because a large amount of ZnO is homogeneously formed in the bulk solution due to very high supersaturation levels.³⁴ Additionally, although the evolution of C_{eq} in **Figure 2** was plotted for a given C_0 of 30 mM, it should be noted here that $C_{eq} \sim 0.5 C_0$ in the C_0 typical range of 10 – 100 mM when no NH_3 is added. In other words, the proportion of remaining Zn(II) species is unchanged when the equimolar concentration of $\text{Zn}(\text{NO}_3)_2$ and HMTA is varied from 10 to 100 mM and when no NH_3 is added. The influence of the homogeneous growth is basically not described by the present model.

Figure 2. Concentrations of dissolved and crystallized Zn(II) ions when thermodynamic equilibrium is reached, as computed with Visual MINTEQ for $C_0 = 30$ mM and $T = 80, 90$ and 95°C . The plotted curve directly gives the value of C_{eq} .

3.2. Investigation of the fundamental physicochemical processes during CBD by using the theoretical model. In order to assess the consistency and reliability of our theoretical model with respect to experimental data, we first consider CBD conditions where the homogeneous growth can be neglected. In that purpose, a first series of samples of ZnO NWs was grown at 90°C in a chemical bath containing 30 mM of $\text{Zn}(\text{NO}_3)_2$ and HMTA as well as 800 mM of NH_3 mixed in aqueous solution, giving rise to an initial pH of 11.0. The total growth time was further varied in the range from 40 min to 8 h. As expected, the length of ZnO NWs continuously increases with growth time, as shown in **Figure 3**. Interestingly, no significant homogeneous growth occurs in the chemical bath under these CBD conditions, even for the growth time of 8 h, as revealed in **Figure S1a-c**. This clearly indicates that the homogeneous growth is overall negligible for the present CBD conditions.

Figure 3. Cross-sectional view FESEM images of ZnO NWs grown by CBD at 90°C with 30 mM of $\text{Zn}(\text{NO}_3)_2$ and HMTA as well as 800 mM of NH_3 for (a) 40 min, (b) 1 h, (c) 1.5 h, (d) 3 h, (e) 5 h and, (f) 8 h, respectively. The scale bar represents $5\ \mu\text{m}$.

The mean length of ZnO NWs as deduced from cross-sectional view FESEM images in **Figure 3** is presented in **Figure 4**, where its evolution as a function of effective growth time is fitted by Eqs.11 and 10 using both theoretical models under static and dynamic conditions, respectively. It should be noted here that the effective growth time is actually introduced by considering the thermalization time of 35 min for the chemical bath to reach 90°C . S values, as deduced from top-view FESEM images in **Figure S2**, are further found to be fairly constant and a mean S value of 0.27 is then considered. The linear fit from Eq.11 yields $R_c^{static} = 1.90\ \mu\text{m/h}$. By using $C_0 = 30$ mM and $\delta = 3.8\ \text{mm}$ ²⁹ along with $D = 2.74 \times 10^{-9}\ \text{m}^2/\text{s}$ ³⁵, a low value of k_1 around $2.28\ \mu\text{m/s}$ is obtained. However, we can immediately notice that the linear fit provided by Eq.11 has a very poor agreement with the experimental data, as it fails to predict the decrease in the axial growth rate of ZnO NWs with effective growth time. In contrast, by setting ΔC and k_1 as the only free fit parameters in Eq.10, a very good agreement with the experimental data is

reached for $\Delta C = 22.4$ mM and $k_1 = 19.4$ $\mu\text{m/s}$. It is worth noticing that thermodynamic calculations predict $\Delta C = 26.2$ mM under these CBD conditions as seen in **Figure 2**, which is in good accordance with the fitted value. The small difference can be explained by a residual homogeneous growth that still occurs in the chemical bath, lowering in turn the available precursor concentration for the elongation process of ZnO NWs on the substrate. As a consequence, the theoretical model under static conditions should only be used to describe the axial growth rate of ZnO NWs in particular cases – as when a continuous flow reactor is used for instance²⁸ – while our theoretical model under dynamic conditions can be applied to describe the axial growth rate of ZnO NWs in the vast majority of cases – as when a sealed reactor is used.

Figure 4. Length versus effective growth time of ZnO NWs grown by CBD at 90 °C with 30 mM of $\text{Zn}(\text{NO}_3)_2$ and HMTA as well as 800 mM of NH_3 . The experimental data were fitted by Eq.11 with $R_c^{\text{static}} = 1.90$ $\mu\text{m/h}$ using the theoretical model under static conditions, and by Eq.10 with $\Delta C = 22.4$ mM, $k_1 = 19.4$ $\mu\text{m/s}$, $S = 0.27$, $D = 2.74 \times 10^{-9}$ m^2/s , and $\rho = 4.20 \times 10^{28}$ m^{-3} using the theoretical model under dynamic conditions, respectively.

As the theoretical model under dynamic conditions has successfully described the evolution of the length of ZnO NWs with growth time when no significant homogeneous growth occurs, we can now use it in more typical, general cases to gain a deeper understanding of the fundamental physicochemical processes in the CBD. In particular, the temperature dependence of the surface reaction rate constant k_1 in Eqs.10 and 11 has not been determined yet despite its strong interest to reveal the mechanisms at work during the elongation process of ZnO NWs. In that purpose, three series of samples were grown respectively at 80, 90 and 95 °C in a chemical bath containing 30 mM of $\text{Zn}(\text{NO}_3)_2$ and HMTA mixed in aqueous solution, giving rise to an initial pH of 6.9. The total growth time was again varied in the range from 40 min to 8 h. As NH_3 is usually not used to perform CBD, it was not added to the chemical bath here. As a result, the homogeneous growth is much more pronounced as seen in

Figure S1d-f and it turns out to mostly occur at the very beginning of the CBD. Therefore, to take into account its influence in the theoretical model under dynamic conditions, we make the assumption that it occurs instantaneously at a growth time $t = 0$. The effective concentration involved in the elongation process of ZnO NWs denoted as ΔC is thus expected to be lower than the predicted value of 14.8 mM for these CBD conditions. Moreover, the equilibrium concentration C_{eq} – and in turn the supersaturation level – is not dependent upon the growth temperature in this range of pH as revealed in **Figure 2**. Then, we also assume that ΔC does not vary with temperature. As expected again, the length of ZnO NWs continuously increases with growth time regardless of the growth temperature, as shown in **Figure 5a-g**, **S3**, and **S4**. The mean length of ZnO NWs as deduced from these cross-sectional view FESEM images is presented in **Figure 5h**, where its evolutions as a function of effective growth time are fitted by Eq.10 using the theoretical model under dynamic conditions. For the same reasons as before, the effective growth time is introduced by subtracting the thermalization time of 35 min to the total growth time and a mean S value of 0.27 is considered. Furthermore, we use $D = 2.38 \times 10^{-9} \text{ m}^2/\text{s}$ at 80 °C, $D = 2.74 \times 10^{-9} \text{ m}^2/\text{s}$ at 90 °C, and $D = 2.93 \times 10^{-9} \text{ m}^2/\text{s}$ at 95 °C.³⁵ For the fitting procedure, only the series at 90 °C with ΔC and k_1 set as the only free fit parameters is first considered, where the relation $3.31 \text{ m}^{-2} \cdot \text{s}^{-1} < \Delta C \cdot k_1 \times 10^{-19} < 5.34 \text{ m}^{-2} \cdot \text{s}^{-1}$ must be fulfilled for the sake of consistency with Ref. ²⁹ (see Supporting Information). A very good agreement with the experimental data is found for $\Delta C = 3.93 \text{ mM}$ and $k_1 = 18.2 \text{ } \mu\text{m/s}$. The strong effect of the homogeneous growth at that pH is seen in the fitted value of ΔC , which is much lower than its predicted value of 14.8 mM by thermodynamic calculations as given in **Figure 2**. Interestingly, it should also be noted that the different growth kinetics at 90 °C with or without the addition of NH_3 originate from the only variation of ΔC , while k_1 keep a similar value in both cases. This suggests that the mechanisms involved during the elongation process of ZnO NWs at low and high pH are similar. Second, the series at 80 and 95 °C are subsequently fitted with $\Delta C = 3.93 \text{ mM}$ and k_1 as the only free fit parameter. A very good agreement with the experimental data is found for $k_1 = 2.65 \text{ } \mu\text{m/s}$ at 80 °C and $k_1 = 40.8 \text{ } \mu\text{m/s}$ at 95 °C, respectively. From these k_1 values in the range of 80 to 95 °C, the Arrhenius plot of k_1 , *i.e.* the graph of $\ln(k_1) = f\left(\frac{1}{T}\right)$, is established in **Figure 5i**. The excellent agreement with the experimental data indicates that the elongation process of ZnO NWs is thermally activated. By using the Arrhenius equation,³⁶ we deduce an activation energy E_A of $198 \pm 24 \text{ kJ/mol}$. This value is higher than the activation energy reported in Ref. ²⁸ using classical crystal growth theory.³⁷ However, their approach only considers the activation

energy required for the direct incorporation of Zn^{2+} ions – which are the dominant Zn(II) species under these CBD conditions – onto the *c*-plane faces of ZnO NWs. In contrast, as Zn^{2+} ions are well-known to form octahedral complexes with water molecules – *i.e.* $[\text{Zn}(\text{H}_2\text{O})_6]^{2+}$ – in aqueous solution,^{38–41} a dehydration step is required before their direct incorporation onto the *c*-plane faces of ZnO NWs. It has been further confirmed that no intermediates in the form of zinc hydroxide phases are involved in the crystallization process for the present CBD conditions.⁴² *Ab initio* calculations have shown that the energy of hydration of six water molecules on a Zn^{2+} ion lies in the range of -1600 to -1400 kJ/mol,^{40,43–46} revealing a very high energy barrier for the complete dehydration of the ion in aqueous solution. However, this barrier is presumably much lower on the *c*-plane faces of ZnO NWs where the dehydration process may be assisted by the surface. Also, a partial dehydration of Zn^{2+} ions might be sufficient for its direct incorporation onto the *c*-plane faces of ZnO NWs, leading in turn to a massive incorporation of hydrogen in their center as reported in Ref. ⁴⁷. Therefore, the relatively high activation energy we obtain is most likely explained by both processes of dehydration of $[\text{Zn}(\text{H}_2\text{O})_6]^{2+}$ ions and of incorporation of Zn(II) species at the *c*-plane top faces of ZnO NWs.

Figure 5. (a-g) Cross-sectional view FESEM images of ZnO NWs grown by CBD at 90 °C with 30 mM of $\text{Zn}(\text{NO}_3)_2$ and HMTA for (a) 40 min, (b) 1 h, (c) 1.5 h, (d) 2 h, (e) 3 h, (f) 5 h, and (g) 8 h, respectively. The scale bar represents 1 μm. (h) Length versus effective growth time of ZnO NWs for each of these series of samples. The experimental data were fitted by Eq.10 with $\Delta C = 3.93$ mM, $S = 0.27$, $\rho = 4.20 \times 10^{28} \text{ m}^{-3}$, and with $k_1 = 2.65$ μm/s and $D = 2.38 \times 10^{-9} \text{ m}^2/\text{s}$ at 80 °C, $k_1 = 18.2$ μm/s and $D = 2.74 \times 10^{-9} \text{ m}^2/\text{s}$ at 90 °C, and $k_1 = 40.8$ μm/s and $D = 2.93 \times 10^{-9} \text{ m}^2/\text{s}$ at 95 °C, using the theoretical model under dynamic conditions. (i) Arrhenius plot of the surface reaction rate constant k_1 of ZnO NWs.

3.3. Effects of the CBD conditions by using the theoretical model as a predictive

approach. As the temperature dependence of k_1 has precisely been established, a predictive approach can be developed to model the elongation process of ZnO NWs in a standard sealed reactor for a broad range of CBD conditions. The concentration profile of Zn(II) species versus effective growth time t and height z above the ZnO NWs, as deduced from Eq.7, is shown in **Figure 6a** for the particular case where the growth temperature is 90 °C, $C_0 = 30$ mM, and $S = 0.27$. The effects of the homogeneous growth at $t = 0$ where the concentration of Zn(II) species instantaneously drops of more than 10 mM everywhere in the chemical bath is clearly seen along with the effect of the equilibrium concentration of Zn(II) species C_{eq} limiting the effective concentration ΔC to only 3.93 mM for the elongation process of ZnO NWs. It is worth noticing that the influence of the homogeneous growth on the value of ΔC was assessed here through the experimental fit in **Figure 5** for a given set of CBD conditions, as it cannot predictively be determined by the present model. However, in a first approximation, ΔC can be inferred in the most widely used case, where the concentration of $\text{Zn}(\text{NO}_3)_2$ and HMTA is equimolar and where no NH_3 is added. In these CBD typical conditions, $C_0 / C_{eq} \sim 2$ as previously discussed in **Figure 2** and hence the supersaturation ratio is unchanged. Accordingly, we may roughly assume in these conditions that $\Delta C \sim 0.13 C_0$ by taking the homogeneous growth into account. Moreover, it should be noted that the concentration profile of Zn(II) species does not reach a steady state as it continuously decreases by increasing the growth time, regardless of the height z above the ZnO NWs. **Figure 6b,c** reveals the evolution of the length of ZnO NWs as a function of effective growth time and temperature, as deduced from Eq.10 in the particular cases where $C_0 = 30$ mM and $S = 0.27$. For each growth temperature, k_1 values were deduced from the linear fit in **Figure 5i** and D values were inferred from Ref. ³⁵. For the sake of clarity, the theoretical data are represented both on 3D (**Figure 6b**) and 2D graphs (**Figure 6c**) at a given temperature in the range of 60 to 95 °C. Below the growth temperature of 60 °C, the NW growth is negligible, while their length rapidly increases for higher temperatures, which is consistent with what is typically observed experimentally in the literature.⁴⁸ Importantly, we further note that the increase in the length of ZnO NWs with the growth temperature has an inflexion point around 75 °C. This directly indicates that, for related higher values of k_1 , the axial growth rate of ZnO NWs is predominantly limited by the diffusive transport of Zn(II) ions. The present predictive approach represents a powerful tool for the optimization of the CBD conditions and the design of a sealed reactor for both fundamental and applied research.

Figure 6. (a) Concentration of Zn(II) species versus effective growth time t and height z above the ZnO NWs, for a chemical bath at 90 °C initially containing 30 mM of $\text{Zn}(\text{NO}_3)_2$ and HMTA. Eq.7 was used for the plot with $\Delta C = 3.93$ mM, $C_{eq} = 15.18$ mM, $k_1 = 18.2$ $\mu\text{m/s}$, $S = 0.27$, $D = 2.74 \times 10^{-9}$ m^2/s , and $\rho = 4.20 \times 10^{28}$ m^{-3} . (b-c) Length of ZnO NWs versus effective growth time t and temperature T , for a chemical bath initially containing 30 mM of $\text{Zn}(\text{NO}_3)_2$ and HMTA. Eq.10 was used for the plot with $\Delta C = 3.93$ mM, $S = 0.27$ and $\rho = 4.20 \times 10^{28}$ m^{-3} . For each growth temperature, k_1 values were deduced from **Figure 5i** and D values were inferred from Ref. ³⁵.

4. CONCLUSIONS

In summary, we have established a theoretical model to describe the elongation process of NWs grown by CBD under dynamic conditions, namely in a sealed reactor where the depletion of chemical reactants occurs. The present experimental configuration is used in the vast majority of investigations reported in the literature and dedicated to the synthesis of ZnO NWs for both fundamental and applied research. Our theoretical model is based on the resolution of Fick's diffusion equations using appropriate boundary conditions in combination with thermodynamic computations yielding the equilibrium concentration of Zn(II) species. The expression of the axial growth rate of ZnO NWs and its temporal dependence is determined, namely the evolution of their length vs growth time. That expression is found to be in very good agreement with a large set of experimental data collected at different pHs and growth temperatures. In particular, we have shown, from the temperature dependence of the surface reaction rate constant k_1 , that the activation energy required for the elongation process of ZnO NWs is equal to 198 ± 24 kJ/mol. The present value typically involves the energy barriers required i) for the dehydration process of Zn(II) species (*i.e.* $[\text{Zn}(\text{H}_2\text{O})_6]^{2+}$ ions), and ii) for their subsequent direct incorporation onto the c -plane faces of ZnO NWs. By using the theoretical model as a predictive approach, a complete growth diagram reporting the evolution of the length of ZnO NWs vs effective growth time and temperature is gained as a typical illustration. Our theoretical model represents a powerful tool for the careful investigation of the physicochemical processes at work during the CBD of ZnO NWs for fundamental research, but also for the design of a sealed reactor or the

predictive behavior in a broad range of CBD conditions for applied research and industrial purposes. Eventually, this general approach is of high potential for other systems involving a wide variety of chemicals in solution and of semiconducting materials grown by CBD.

SUPPORTING INFORMATION

Detailed proof of the dynamic growth model, pictures of the chemical bath, top-view FESEM images of the series at 90 °C with 800 mM of NH₃, cross-sectionial view FESEM images of the series at 80 and 95 °C, NW length and *S* numerical values of the series at 80, 90 and 95 °C (PDF).
