Preface

Our aim in writing this book is to present a clear introduction to algebraic number theory at the upper undergraduate/graduate level. The first chapters are devoted to elementary Galois theory, which plays a fundamental role in algebraic number theory. Usually the Galois theory needed in algebraic number theory is confined to a reference or a brief appendix. We feel it is useful to have a good treatment of this material at hand. Naturally, there are important parts of Galois theory, for example radical extensions and inverse Galois theory, which we do not handle, as they do not concern the main subject of this text.

After this preliminary work we turn to the study of algebraic number fields, i.e., finite field extensions of the rationals, presenting basic results such as the Kronecker-Weber theorem, Dedekind’s different theorem, Dirichlet’s unit theorem, Hermite’s theorem and Dedekind’s factorization theorem. We also introduce and study the class group of a number ring and establish the class number formula. In general, our proofs are detailed and we do not leave important parts of proofs to the reader. This avoids tedious reading and frustration when faced with gaps which the reader is often unable to fill in.

As for required reading, we assume a good background in elementary algebra: semigroups, groups, rings and modules over rings; in particular, the basic isomorphism theorems for groups, rings and modules. We also assume a basic knowledge of Lebesgue integration and complex analysis. Finally, we suppose that the reader is acquainted with fundamental number theory, for example the rings of integers $\mathbb{Z}_n$ and the finite fields $\mathbb{F}_p$. All this material is generally covered in the first years of a mathematics program. Of course, where necessary, we give reminders; however, as our aim is to reach a relatively high level in a moderately short text, we do not spend too much time on elementary notions.

Unless otherwise mentioned, we will suppose that all rings are commutative with identity, although we will often recall these assumptions.

## Preface

### I Elementary Galois Theory

1 Field Extensions
   - 1.1 Prime fields
   - 1.2 Algebraic extensions
   - 1.3 Algebraic numbers

2 Splitting fields
   - 2.1 Existence of finite fields
   - 2.2 Algebraic closures

3 Separability
   - 3.1 Separable polynomials
   - 3.2 Separable extensions
   - 3.3 Transitivity of separability

4 Properties of finite fields

5 Normal extensions
   - 5.1 Normal closures

6 The Galois group
   - 6.1 Fundamental theorem of Galois theory
   - 6.2 Composita
   - 6.3 The fundamental theorem of algebra
   - 6.4 Normal closures

7 The Galois group of a polynomial
   - 7.1 Irreducible polynomials
   - 7.2 Cyclotomic extensions
   - 7.3 Cyclotomic polynomials
   - 7.4 Cyclotomic extensions of the rationals
   - 7.5 Cyclotomic extensions of finite fields
   - 7.6 Quadratic and cyclotomic extensions
   - 7.7 Orbits of the Galois group action
E  Free abelian groups and free modules  327
F  The Chinese remainder theorem  336
G  Lattices in euclidian space  338
H  Kronecker products of matrices  346
I  Infinite products  349
Part I

Elementary Galois Theory
Chapter 1

Field Extensions

If $E$ and $F$ are rings, in particular fields, then we say that $E$ is an extension of $F$, or $F$ is included in $E$, if there is an injective ring homomorphism $\phi$, or monomorphism, from $F$ into $E$. The following result justifies these terms.

**Theorem 1.1** Let $\phi$ be a monomorphism of the ring $A$ into the ring $B$. Then there is an extension $\bar{A}$ of $A$ and of $\phi$ to an isomorphism of $\bar{A}$ onto $B$.

**Proof** If $\phi : A \rightarrow B$ is an isomorphism, then there is nothing to prove, so we can suppose that this is not the case. We set $\bar{A} = A \cup B \setminus \phi(A)$ and then define $\psi : B \rightarrow \bar{A}$ by

$$\psi(y) = \begin{cases} \phi^{-1}(y) & \text{if } y \in \phi(A), \\ y & \text{if } y \notin \phi(A). \end{cases}$$

$\phi$ is clearly a bijection. We define an addition $\bar{+}$ and a multiplication $\bar{}$ on $\bar{A}$ by

$$x_1 \bar{+} x_2 = \psi(\psi^{-1}(x_1) + \psi^{-1}(x_2)) \quad \text{and} \quad x_1 \bar{} x_2 = \psi(\psi^{-1}(x_1) \cdot \psi^{-1}(x_2)).$$

It is easy to check that $\psi(1) = 1$. Thus $\bar{A}$ with the operations just defined is a ring which is isomorphic to $B$. What remains to be shown is that the operations $\bar{+}$ and $\bar{}$ restricted to $A$ are the ring operators $+$ and $\cdot$ of $A$. If $\phi(x_1) = y_1$ and $\phi(x_2) = y_2$, then

$$x_1 \bar{+} x_2 = \psi(y_1 + y_2) = \psi(\phi(x_1) + \phi(x_2)) = \psi(\phi(x_1) + \phi(x_2)) = x_1 + x_2.$$

A similar calculation gives $x_1 \bar{} x_2 = x_1 \cdot x_2$. Hence $\bar{A}$ is an extension of $A$ and $\bar{\phi} = \psi^{-1}$ is an isomorphism from $\bar{A}$ onto $B$. $\square$

When the ring $B$ is an extension of the ring $A$ as defined above we will often write $B/A$.

We recall that, if $F$ is a field, then the ring $F[X]$ of polynomials with coefficients in $F$ is a PID (principal ideal domain). For $f \in F[X]$ we write $(f)$ for the ideal generated by $f$, i.e.,

$$(f) = \{gf : g \in F[X]\},$$

8
monic and irreducible, then $F\alpha$ root in an extension of $E$

Exercise 1.2

Let $g$ be an irreducible factor of $f$. From the previous proposition we know that $E = R_g$ is a field. As the mapping $\phi : F \rightarrow R_g, a \mapsto a + (g)$ is a monomorphism, $E$ is an extension of $F$. If $g = \sum_{k=0}^{s} a_k X^k$ and $\alpha = X + (g)$, then in $E$

$$g(\alpha) = \sum_{k=0}^{s} (a_k + (g))\alpha^k = g + (g) = 0.$$  

As $g(\alpha) = 0$ in $E$ and $g$ divides $f$, $f(\alpha) = 0$ in $E$. 

Exercise 1.2 Let $f, g \in F[X]$. Show that $\gcd(f, g) = 1$ if and only if $f$ and $g$ have no common root in an extension of $F$. Deduce that if $f \neq g$ are nonconstant polynomials in $F[X]$, which are monic and irreducible, then $f$ and $g$ have no common root in an extension of $F$.

If $E$ is an extension of $F$ and $\alpha \in E$, then we write $F(\alpha)$ for the smallest subfield of $E$ containing $F$ and $\alpha$, i.e., the intersection of all subfields of $E$ containing $F$ and $\alpha$. In fact, $F(\alpha)$ is the collection of all fractions of the form $\frac{f(\alpha)}{g(\alpha)}$, where $f, g \in F[X]$ and $g(\alpha) \neq 0$. We also say that $F(\alpha)$ is the subfield of $E$ generated by $F$ and $\alpha$. 

Theorem 1.2 If $f \in F[X]$, with $\deg f \geq 1$, then there is an extension $E$ of $F$ which contains a root of $f$. 

Proof Let $g$ be an irreducible factor of $f$. From the previous proposition we know that $E = R_g$ is a field. As the mapping $\phi : F \rightarrow R_g, a \mapsto a + (g)$ is a monomorphism, $E$ is an extension of $F$. If $g = \sum_{k=0}^{s} a_k X^k$ and $\alpha = X + (g)$, then in $E$

$$g(\alpha) = \sum_{k=0}^{s} (a_k + (g))\alpha^k = g + (g) = 0.$$  

As $g(\alpha) = 0$ in $E$ and $g$ divides $f$, $f(\alpha) = 0$ in $E$. 

Exercise 1.2 Let $f, g \in F[X]$. Show that $\gcd(f, g) = 1$ if and only if $f$ and $g$ have no common root in an extension of $F$. Deduce that if $f \neq g$ are nonconstant polynomials in $F[X]$, which are monic and irreducible, then $f$ and $g$ have no common root in an extension of $F$.
1.1 Prime fields

In this section we will show that every field can be considered as an extension of the rational numbers \( \mathbb{Q} \) or of a field \( \mathbb{F}_p \), for a certain prime number \( p \). We begin with a preliminary result.

**Proposition 1.2** Let \( R \) be a subring of a field \( F \) and \( K \) the intersection of all the subfields of \( F \) which contain \( R \). Then \( K = \text{Frac}(R) \), the field of fractions of \( R \).

**Proof** As \( R \) is a subring of \( F \), \( R \) is an integral domain and so \( \text{Frac}(R) \) is a field. We can define a monomorphism \( \phi \) from \( \text{Frac}(R) \) into \( F \) in the following way:

\[
\phi(a) = a \quad \forall a \in R \quad \text{and} \quad \phi\left(\frac{a}{b}\right) = \phi(a)\phi(b)^{-1}.
\]

We set \( L = \text{Im} \phi \). Then \( L \) is a subfield of \( F \) containing \( R \), hence \( K \subseteq L \). In addition, if \( G \) is a subfield of \( F \) which contains \( R \), then \( G \) contains any element of the form \( \phi(a)\phi(b)^{-1} \), with \( b \neq 0 \), because \( G \) is a field and \( \phi(R) = R \). Therefore \( L \subseteq G \). It follows that \( L \subseteq K \). Thus \( K = L \equiv \text{Frac}(R) \).

The intersection of all the subfields of a given field \( F \) is itself a subfield of \( F \), called the prime field of \( F \). Clearly \( F \) is an extension of its prime subfield.

**Theorem 1.3** The prime subfield of a field \( F \) is isomorphic to \( \mathbb{Q} \) or to \( \mathbb{F}_p \) for some prime number \( p \).

**Proof** Let \( \phi \) be the mapping of \( \mathbb{Z} \) into \( F \) defined by \( \phi(n) = n.1 \), where 1 is the identity for the multiplication in \( F \). It is easy to see that \( \phi \) is a ring homomorphism. We write \( I = \ker \phi \). Then \( I \) is an ideal of \( \mathbb{Z} \) and the factor ring \( \mathbb{Z}/I \) is isomorphic to a subring of \( F \), therefore \( \mathbb{Z}/I \) is an integral domain, which implies that \( I \) is a prime ideal in \( \mathbb{Z} \). As \( \phi \) is not the zero mapping, \( I = (0) \) or \( I = (p) \), where \( p \) is a prime number.

In the first case \( \phi \) is injective and the subring \( \phi(\mathbb{Z}) \) of \( F \) is included in \( P \), the prime field of \( F \). From Proposition 1.2 above, \( P \) is isomorphic to \( \text{Frac}(\phi(\mathbb{Z})) \), which is clearly isomorphic to \( \mathbb{Q} \).

If \( I = (p) \), then \( \phi(\mathbb{Z}) \) is isomorphic to \( \mathbb{Z}/(p) \), which is \( \mathbb{F}_p \). However, \( \phi(\mathbb{Z}) \) is included in every subfield of \( F \) and so \( \phi(\mathbb{Z}) \subseteq P \); but \( \phi(\mathbb{Z}) \) is a subfield of \( F \), hence \( P \subseteq \phi(\mathbb{Z}) \). Thus \( P \) is isomorphic to \( \mathbb{F}_p \).

This theorem has an important corollary, namely

**Corollary 1.1** If \( F \) is a finite field, then the cardinal of \( F \) is \( p^k \), where \( p \) is a prime number and \( k \) a positive integer.

**Proof** The prime subfield \( P \) of \( F \) must be finite, hence of the form \( \mathbb{F}_p \), for some prime number \( p \). If \( [F : \mathbb{F}_p] = k \), then \( |F| = p^k \).

Some final remarks before closing this section. It should be clear that, if one field is an extension of another, then they both have the same prime field. Also, if \( \mathbb{Q} \) is the prime field of a given field \( F \), then the characteristic of \( F \) is 0. On the other hand, if the prime field is \( \mathbb{F}_p \), then the characteristic of \( F \) is \( p \).
1.2 Algebraic extensions

If $E$ is an extension of $F$ and $\alpha \in E$ is a root of a nonconstant polynomial $f \in F[X]$, then we say that $\alpha$ is algebraic over $F$. If $\alpha$ is not algebraic, then we say it is transcendental. If every element of $E$ is algebraic, then we say that $E$ is an algebraic extension. An extension which is not algebraic is said to be a transcendental extension.

**Proposition 1.3** If $[E : F] < \infty$, then $E$ is an algebraic extension of $F$.

**Proof** Let $\alpha \in E$ and $[E : F] = n$. The vectors $1, \alpha, \ldots, \alpha^n$ are dependant and so we can find $a_0, a_1, \ldots, a_n \in F$ not all equal to 0 such that $\sum_{i=0}^{n} a_i \alpha^i = 0$. Hence $\alpha$ is a root of the polynomial $f(X) = \sum_{i=0}^{n} a_i X^i$. \qed

**Corollary 1.2** If an extension is not algebraic, then it is infinite-dimensional.

**Proof** Let $E/F$ be an extension which is not algebraic. By hypothesis, there exists $\alpha \in E$ which is not algebraic over $F$. If $[E : F] < \infty$, then, from Proposition 1.3, $E$ is an algebraic extension of $F$, so $\alpha$ is algebraic over $F$, a contradiction. It follows that $E/F$ is infinite-dimensional. \qed

**Remark** We will see below that the converse of Proposition 1.3 is false (example after Corollary 1.5).

If $E$ is an extension of $F$ and $\alpha \in E$ is algebraic over $F$, then the collection of polynomials $f \in F[X]$ such that $f(\alpha) = 0$ form an ideal $I$ in $F[X]$. The unique monic generator of $I$, which we note $m(\alpha, F)$, or simply $m$ if the field $F$ is understood, is called the minimal polynomial of $\alpha$ over $F$. A minimal polynomial is clearly irreducible. It should also be noticed that if $K/F, E/K$ and $\alpha \in E$ is algebraic over $F$, then $\alpha$ is also algebraic over $K$, since $m(\alpha, F) \in K[X]$.

**Proposition 1.4** If $E$ is an extension of $F$, $\alpha \in E$ and $\deg m(\alpha, F) = n$, then $[F(\alpha) : F] = n$.

**Proof** We will first show that $F_{n-1}[\alpha]$, the set of polynomials in $\alpha$ of degree strictly less than $n$ is a field and thus is equal to $F(\alpha)$. If $f \in F[X]$ then we may find $g, r \in F[X]$, with $\deg r < n$ such that

$$f(X) = g(X)m(X) + r(X) \implies f(\alpha) = g(\alpha)m(\alpha) + r(\alpha) = r(\alpha).$$

Now if $f_1, f_2 \in F[X]$ and we set $f = f_1 f_2$, then we may find $r \in F_{n-1}[X]$ such that $f(\alpha) = r(\alpha)$; therefore $F_{n-1}[\alpha]$ is closed under multiplication. Clearly $F_{n-1}[\alpha]$ is closed under addition. It follows that $F_{n-1}[\alpha]$ is a subring of $F(\alpha)$. To show that it is a field we only need to find an inverse for every nonzero element. If $f \in F_{n-1}(X)$ and $f \neq 0$, then $\deg f < \deg m$. As $m$ is irreducible we may find $g, h \in F[X]$ such that

$$f(X)g(X) + m(X)h(X) = 1 \implies f(\alpha)g(\alpha) = 1.$$

However, we have seen that there is $s \in F_{n-1}[X]$ such that $s(\alpha) = g(\alpha)$, hence $f(\alpha)$ has an inverse. We have shown that $F_{n-1}[\alpha] = F(\alpha)$. As the vectors $1, \alpha, \ldots, \alpha^{n-1}$ are independant and $\alpha^n$ is a linear combination of smaller powers of $\alpha$, these vectors form a basis of $F_{n-1}[\alpha]$; it follows that $[F(\alpha) : F] = n$. \qed

**Corollary 1.3** If $\alpha$ is algebraic over $F$, then $F(\alpha)$ is an algebraic extension of $F$.
Remark In the course of the proof of Proposition 1.4 we have shown that, if \( \alpha \) is algebraic, then \( F(\alpha) = F[\alpha] \).

As examples of algebraic extensions we will consider quadratic number fields. We say that a finite extension \( E \) of \( \mathbb{Q} \) in \( \mathbb{C} \) is a \textit{number field}. It is quadratic if the degree of the extension is 2. Suppose that \( d \in \mathbb{Z} \) is not a square and let \( \alpha \) be a square root of \( d \). If \( d > 0 \), then we usually suppose that \( \alpha \) is the positive root, and if \( d < 0 \), then \( \alpha \) is the product of \( i \) and the positive root of \( -d \). In both cases we write \( \sqrt{d} \) for \( \alpha \). If \( \sqrt{d} = \frac{a}{b} \in \mathbb{Q} \), then \( b^2d = a^2 \), which is impossible because \( d \) is not a square. It follows that \( \deg m(d, \mathbb{Q}) > 1 \). As \( \sqrt{d} \) is a root of the polynomial \( P(X) = -d + X^2 \), we have \( P(X) = m(\sqrt{d}, \mathbb{Q}) \). It follows that \( |\mathbb{Q}(\sqrt{d}) : \mathbb{Q}| = 2 \) and that \( (1, \sqrt{d}) \) is a basis of \( \mathbb{Q}(\sqrt{d}) \) over \( \mathbb{Q} \).

If \( d \) is a square, then \( \sqrt{d} \in \mathbb{Z} \) and so \( \mathbb{Q}(\sqrt{d}) = \mathbb{Q} \), so we exclude this case. On the other hand, if \( d = u^2v \), where \( v \) is square-free, then \( \mathbb{Q}(\sqrt{d}) = \mathbb{Q}(\sqrt{v}) \), so we can limit our attention to square-free integers \( d \). The following result is a little unexpected.

**Theorem 1.4** If \( m \) and \( n \) are square-free integers and \( m \neq n \) then \( \mathbb{Q}(\sqrt{m}) \) is not isomorphic to \( \mathbb{Q}(\sqrt{n}) \).

**Proof** Suppose that there is an isomorphism \( \phi \) from \( \mathbb{Q}(\sqrt{m}) \) onto \( \mathbb{Q}(\sqrt{n}) \). As \( \phi(1) = 1 \), \( \phi \) must fix all elements of \( \mathbb{Q} \). Let \( \phi(\sqrt{m}) = a + b\sqrt{n} \). If \( b = 0 \), we have a \( \phi(a) = a = \phi(\sqrt{m}) \), which contradicts the fact that \( \phi \) is injective, so \( b \neq 0 \). Also

\[
m = \phi(m) = \phi((\sqrt{m})^2) = (\phi(\sqrt{m}))^2 = (a + b\sqrt{n})^2 = a^2 + 2ab\sqrt{n} + b^2n.
\]

If \( a \neq 0 \), then \( \sqrt{n} = \frac{m-a^2-b^2n}{2ab} \in \mathbb{Q} \), a contradiction. Hence \( a = 0 \) and \( m = b^2n \). If \( b = \frac{e}{f} \), with \( (e, f) = 1 \), then we have \( e^2m = f^2n \), which is only possible if \( e^2 = f^2 \), because \( m \) and \( n \) are square-free. It follows that \( b^2 = 1 \) and so \( m = n \). \( \square \)

A little later we will see that all quadratic number fields are of the form we have seen here.

Suppose that \( F, K \) and \( E \) are fields with \( K \) an extension of \( F \) and \( E \) an extension of \( K \). We now consider the relation between the degrees of the extensions. We recall that any vector space over a field has a basis which may be infinite.

**Proposition 1.5** If \((\beta_j)_{j \in J}\) is a basis of \( K \) over \( F \) and \((\alpha_i)_{i \in I}\) a basis of \( E \) over \( K \), then \((\alpha_i\beta_j)_{i \in I, j \in J}\) is a basis of \( E \) over \( F \).

**Proof** If \( \gamma \in E \), then \( \gamma \) is a linear combination of \( \alpha_i \), with coefficients \( a_i \in K \). As each \( a_i \) is a linear combination of \( \beta_j \), with coefficients \( b_j \in F \), \( \gamma \) is a linear combination of \( \alpha_i\beta_j \), with coefficients in \( F \). Thus the set \((\alpha_i\beta_j)_{i \in I, j \in J}\) generates \( E \). To show that it is a basis of \( E \) over \( F \), we must show that it is independent. To do so, let us consider a (finite) linear combination

\[
\sum \lambda_{ij}\alpha_i\beta_j, \text{ with } \lambda_{ij} \in F, \text{ whose value is 0. Adding some terms } \lambda_{ij}\alpha_i\beta_j, \text{ with } \lambda_{ij} = 0 \text{ if necessary, we may write}
\]

\[
0 = \sum_{i,j} \lambda_{ij}\alpha_i\beta_j = \sum_i \left( \sum_j \lambda_{ij}\beta_j \right) \alpha_i.
\]

As the \( \alpha_i \) are independent, \( \sum_j \lambda_{ij}\beta_j = 0 \) for every \( i \). However, the \( \beta_j \) are independent and so \( \lambda_{ij} = 0 \), for each pair \((i, j)\). Hence the elements \( \alpha_i\beta_j \) form an independent collection. We have shown that \((\alpha_i\beta_j)_{i \in I, j \in J}\) is a basis of \( E \) over \( F \). \( \square \)

This leads to the following statement, often referred to as the \textit{multiplicativity of the degree:}
Corollary 1.4 If $K/F$ and $E/K$, then

$$[E : F] = [E : K][K : F].$$

Suppose now that $E$ is an extension of $F$ and that $\alpha_1, \ldots, \alpha_n \in E$. We denote $F(\alpha_1, \ldots, \alpha_n)$ the subfield of $E$ generated by $F$ and the $\alpha_i$, i.e., the smallest subfield of $E$ containing $F$ and the $\alpha_i$. (We have already seen this notion when there is only one $\alpha_i$.) In fact, this field is the collection of all fractions of the form $\frac{f(\alpha_1, \ldots, \alpha_n)}{g(\alpha_1, \ldots, \alpha_n)}$, where $f, g \in F[X_1, \ldots, X_n]$ and the denominator is nonzero. We may generalize Corollary 1.3.

Corollary 1.5 If $\alpha_1, \ldots, \alpha_n$ are algebraic over $F$, then $F(\alpha_1, \ldots, \alpha_n)$ is a finite extension of $F$, hence an algebraic extension of $F$. Moreover, $F(\alpha_1, \ldots, \alpha_n) = F[\alpha_1, \ldots, \alpha_n]$.

**Proof** Let us set

$$E_0 = F, E_1 = F(\alpha_1), E_2 = F(\alpha_1, \alpha_2), \ldots, E_n = F(\alpha_1, \alpha_2, \ldots, \alpha_n).$$

Then $E_k = E_{k-1}(\alpha_k)$ and $\alpha_k$ is algebraic over $E_{k-1}$. Now $[E_k : E_{k-1}] = \deg m(\alpha_k, E_{k-1})$ and

$$[E_n : F] = \prod_{k=0}^{n-1} [E_{k+1} : E_k] < \infty,$$

the result we were looking for.

To prove the second statement we use a simple induction argument. We have already seen that it is true for $n = 1$. (See the remark after Corollary 1.3). If we suppose that the statement is true up to $n-1$, then we have

$$F(\alpha_1, \ldots, \alpha_n) = F(\alpha_1, \ldots, \alpha_{n-1})(\alpha_n) = F(\alpha_1, \ldots, \alpha_{n-1}|\alpha_n) = F[\alpha_1, \ldots, \alpha_{n-1}, \alpha_n],$$

which concludes the induction step and hence the proof.

**Example** Consider the extension $E = \mathbb{Q}(\sqrt[3]{2} : n \in \mathbb{N}^*)$ of $\mathbb{Q}$. Any element $\alpha \in E$ is algebraic over $\mathbb{Q}$, because $\alpha \in \mathbb{Q}(\sqrt[3]{2} : n = 1, \ldots, N)$, for some $N \in \mathbb{N}^*$, and $\sqrt[3]{2}$ is algebraic over $\mathbb{Q}$. Hence $E$ is an algebraic extension of $\mathbb{Q}$. For any $n \in \mathbb{N}^*$, by the Eisenstein criterion, $f_n(X) = -2 + X^n$ is irreducible and hence the minimal polynomial of $\sqrt[3]{2}$. However, $E_n \subset E$, where $E_n = \mathbb{Q}(\sqrt[3]{2})$, and, from Proposition 1.4, $[E_n : \mathbb{Q}] = n$. This implies that $[E : \mathbb{Q}] \geq n$, for all $n \in \mathbb{N}^*$. Thus we have found an algebraic extension of $\mathbb{Q}$, which is not finite.

We will see later that we may partially rectify this situation by imposing conditions on the algebraic extension.

If $E$ is an extension of $F$ then we will write $A(E/F)$ (or simply $A$ when the fields $E$ and $F$ are understood) for the collection of elements of $E$ which are algebraic over $F$.

**Proposition 1.6** $A(E/F)$ is a subfield of $E$. 

13
PROOF It is sufficient to show that if \( \alpha, \beta \in A \), then \( \alpha, -\alpha, \alpha + \beta, \alpha \beta \) and \( \beta^{-1} \), with \( \beta \neq 0 \), belong to \( A \). However, \( F(\alpha, \beta) \) is an algebraic extension of \( F \), therefore \( F(\alpha, \beta) \subset A \). As \( \alpha, -\alpha, \alpha + \beta, \alpha \beta, \beta^{-1} \in F(\alpha, \beta) \), these elements belong to \( A \). \( \square \)

Remark Proposition 1.6 ensures that \( A(C/Q) \) is an algebraic extension of \( Q \). It contains all the algebraic extensions of \( Q \) and is an infinite extension, after the example following Corollary 1.5.

Exercise 1.3 We have seen that if \( \alpha \) and \( \beta \) are algebraic, then \( \alpha + \beta \) and \( \alpha \beta \) are algebraic. Prove the converse, namely, if \( \alpha + \beta \) and \( \alpha \beta \) are algebraic, then \( \alpha \) and \( \beta \) are algebraic.

We may define a relation \( R \) on the collection of fields by \( FE \) if \( E \) is an algebraic extension of \( F \). This relation is in fact a partial order. Clearly \( R \) is reflexive and antisymmetric, so we only need to show that it is transitive. To do so we need the following preliminary result.

Proposition 1.7 If \( K \) is an algebraic extension of \( F \), \( E/K \) and \( \alpha \in E \) is algebraic over \( K \), then \( \alpha \) is algebraic over \( F \).

Proof Let \( m(\alpha, K) = \sum_{i=0}^{n} a_i X^i \), with \( a_i \in K \), for \( i = 0, \ldots, n \), and \( a_n = 1 \). As the \( a_i \), for \( i = 0, \ldots, n \), are algebraic over \( F \), \( A = F(a_0, a_1, \ldots, a_{n-1}) \) is a finite extension of \( F \), by Corollary 1.5. Now, \( \alpha \) is algebraic over \( A \), therefore \( A(\alpha) \) is a finite extension of \( A \), by Proposition 1.4. Corollary 1.4 ensures that \( A(\alpha) \) is a finite extension of \( F \). Proposition 1.3 now implies that \( \alpha \) is algebraic over \( F \). \( \square \)

Corollary 1.6 The relation \( R \) is transitive, hence a partial order.

Exercise 1.4 Suppose that \( E \) is an algebraic extension of \( F \) and that \( R \) is a ring containing \( F \) and included in \( E \), i.e., \( F \subset R \subset E \). Show that \( R \) is a field.

1.3 Algebraic numbers

An element \( \alpha \in C \) which is algebraic over \( Q \) is said to be an algebraic number. This is equivalent to saying that there is a polynomial \( f \in \mathbb{Z}[X] \) such that \( f(\alpha) = 0 \). If \( \alpha \in C \) is not algebraic then we call \( \alpha \) a transcendental number. We aim to show that \( A(C/Q) \) is countable.

Proposition 1.8 Let \( (E_n)_{n \in \mathbb{N}} \) be a countable collection of countable subsets of a set \( E \). Then the union \( S = \bigcup_{n \in \mathbb{N}} E_n \) is countable.

Proof We set \( F_0 = E_0 \) and \( F_n = E_n \setminus (E_0 \cup E_1 \cup \cdots \cup E_{n-1}) \), for \( n > 0 \). Then \( S = \bigcup_{n \in \mathbb{N}} F_n \) and, if \( m \neq n \), then \( F_m \cap F_n = \emptyset \). Let \( f_n : E_n \to \mathbb{N} \) be an injection and let us set, for \( x \in F_n \), \( f(x) = (n, f_n(x)) \). It is not difficult to see that \( f \) is an injection from \( S \) into \( \mathbb{N}^2 \). As \( \mathbb{N}^2 \) is countable, \( S \) is countable. \( \square \)

Corollary 1.7 The collection of polynomials \( \mathbb{Z}[X] \) is countable.

Proof We note \( P_d \) the subset of \( \mathbb{Z}[X] \) composed of polynomials whose degree is \( d \geq 0 \). We obtain a bijection of \( P_d \) into \( \mathbb{Z}^{d+1} \) by associating to each polynomial \( f \) its sequence of coefficients \( (a_0, a_1, \ldots, a_d) \). As \( \mathbb{Z}^{d+1} \) is countable, \( P_d \) is also countable. From the previous proposition \( \bigcup_{d \in \mathbb{N}} P_d \) is countable. If we now add the polynomial 0, we obtain the result. \( \square \)

We may now prove the result mentioned in the first paragraph.
Theorem 1.5 $A(\mathbb{C}/\mathbb{Q})$ is countable.

Proof From the previous corollary we know that $\mathbb{Z}[X]$ is countable. The subset of $\mathbb{Z}[X]$ composed of nonconstant polynomials is also countable: we may number these polynomials $f_0, f_1, \ldots$. For each $k \in \mathbb{N}$, let $R_k$ be the (finite) set of roots of $f_k$. Then, from Proposition 1.8, $A(\mathbb{C} \setminus \mathbb{Q}) = \bigcup R_k$ is countable. \qed

Corollary 1.8 The collection of transcendental numbers is not countable.

As $A(\mathbb{C}/\mathbb{Q})$ is a field, it is easy to construct algebraic numbers. For example, $\sqrt{2}$ and $\sqrt{3}$ are algebraic numbers, hence their sum, $\sqrt{2} + \sqrt{3}$, is also an algebraic number. Although the transcendental numbers form a much larger set, it is not easy to find explicit examples. We know that $e$ and $\pi$ are transcendental, however the proofs are not easy, in particular for $\pi$. It is an open question whether the following numbers are transcendental or not: $\pi + e$, $\pi - e$, $\pi e$, $\frac{\pi}{e}$, $\pi^e$, $e^\pi$, and $\pi e$.

Exercise 1.5 Show that, if $\alpha$ and $\beta$ are both transcendental, then either $\alpha + \beta$ or $\alpha \beta$ is transcendental.
Chapter 2

Splitting fields

Let $E$ be an extension of the field $F$ and $f \in F[X]$. We say that $f$ splits in $E$, if we can write

$$f(X) = \lambda(X - \alpha_1) \cdots (X - \alpha_n),$$

with $\lambda \in F$ and $\alpha_1, \ldots, \alpha_n \in E$. Such a field always exists: it is sufficient to apply Theorem 1.2 an appropriate number of times. We say that an extension $E$ of $F$ is a splitting field of $f \in F[X]$ if $f$ splits in $E$ and does not do so in any proper subfield of $E$.

**Proposition 2.1** Let $E$ be an extension of $F$ such that $f \in F[X]$ splits in $E$:

$$f(X) = \lambda(X - \alpha_1) \cdots (X - \alpha_n).$$

Then $E$ is a splitting field of $f$ if and only if $E = F(\alpha_1, \ldots, \alpha_n)$.

**Proof** Suppose first that $E$ is a splitting field of $f$. Then $E$ contains $F$ and the elements $\alpha_1, \ldots, \alpha_n$, therefore $F(\alpha_1, \ldots, \alpha_n) \subset E$. As $f$ does not split in any proper subfield of $E$, we must have equality.

Now suppose that $E = F(\alpha_1, \ldots, \alpha_n)$ and let $G$ be a subfield of $E$ such that $f$ splits in $G$. Then $G$ contains $F$ and the elements $\alpha_1, \ldots, \alpha_n$, hence $F(\alpha_1, \ldots, \alpha_n) \in G$. It follows that $E \subset G$ and so $E = G$. Thus $E$ is a splitting field of $f$. \qed

**Corollary 2.1** If $f \in F[X]$ splits in an extension $E$ of $F$, then $E$ contains a unique splitting field of $f$, namely $F(\alpha_1, \ldots, \alpha_n)$.

We can obtain an explicit presentation of a splitting field.

**Proposition 2.2** The splitting field $S$ of $f \in F[X]$ in an extension $E$ of $F$ can be written

$$S = F(\alpha_1, \ldots, \alpha_n) = F[\alpha_1, \ldots, \alpha_n],$$

i.e., $S$ is composed of the polynomials in the roots $\alpha_i$, with coefficients in $F$.

**Proof** The splitting field $S$ of $f$ clearly has the form $F(\alpha_1, \ldots, \alpha_n)$. As for the second equality, we only need to notice that the roots $\alpha_1, \ldots, \alpha_n$ are algebraic over $F$ and then apply Corollary 1.5. \qed

If $E$ is a splitting field of $f \in F[X]$, then we can say something about order of the extension.
Theorem 2.1 If \( f \in F[X] \) and \( \deg f = n \), then there is a splitting field \( E \) of \( f \) such that \( [E : F] \leq n! \).

Proof If \( \deg f = 0 \), then \( f \) is constant and we can take \( E = F \). Now let us suppose that \( \deg f = n \geq 1 \). From Proposition 1.2 we know that there is an extension \( E' \) of \( F \) which contains a root \( \alpha \) of \( f \). The minimal polynomial \( m = m(\alpha, F) \) divides \( f \), so \( \deg m \leq \deg f \). Now, from Proposition 1.4, \( [F(\alpha) : F] = \deg m \), so there exists an extension \( E_1 \) of \( F \) which contains a root \( \alpha_1 \) of \( f \) and is such that with \( [E_1 : F] \leq n \). In \( E_1 \) we can write \( f(Y) = (Y - \alpha_1)^{r_1}q(Y) \), where \( r_1 \geq 1 \) and \( g(\alpha_1) \neq 0 \). If \( g \) is not constant, then we can find an extension \( E_2 \) of \( E_1 \) which contains a root \( \alpha_2 \) of \( g \) (and hence of \( f \)) and is such that \( [E_2 : E_1] \leq n - 1 \). \( E_2 \) is an extension of \( F \) which contains \( \alpha_1 \) and \( \alpha_2 \) and \( [E_2 : F] = [E_2 : E_1][E_1 : F] \leq (n - 1)n \). Continuing in the same way we obtain an extension \( E \) of \( F \) in which \( f \) splits and such that \( [E : F] \leq n! \). To finish it is sufficient to notice that \( E \) contains a splitting field of \( f \).

We have seen that every polynomial has a splitting field. We now aim to show that all such fields are isomorphic. We will begin with two preliminary results.

Lemma 2.1 Let \( f \in F[X] \) be irreducible and \( E \) an extension of \( F \) which contains a root \( \alpha \) of \( f \). Then there is an isomorphism

\[
\Phi : F[X]/(f) \rightarrow F(\alpha)
\]

which fixes \( F \), i.e., for \( g \) constant, \( \Phi(g + (f)) = g \), and such that \( \Phi(X + (f)) = \alpha \).

Proof The mapping \( \phi : F[X] \rightarrow E \) defined by \( \phi(g) = g(\alpha) \) is a ring homomorphism. As \( f \) is irreducible and \( f \in \text{Ker} \phi \), we have \( \text{Ker} \phi = (f) \). It follows that the mapping

\[
\Phi : F[X]/(f) \rightarrow \text{Im} \phi, g + (f) \mapsto \phi(g)
\]

is a ring isomorphism which fixes \( F \). In addition,

\[
\text{Im} \Phi = \text{Im} \phi = \{g(\alpha) : g \in F[X]\} \subset F(\alpha).
\]

(2.1)

As \( f \) is irreducible, \((f)\) is maximal and so \( F[X]/(f) \) is a field. Thus \( \text{Im} \Phi \) a field. However, \( F \) and \( \alpha \) belong to \( \text{Im} \Phi \), which implies that \( F(\alpha) \subset \text{Im} \Phi \). From the equation (2.1) we obtain equality.

\[ \square \]

Lemma 2.2 Let \( R \) and \( S \) be rings, \( I \) is an ideal of \( R \) and \( J \) an ideal of \( S \). If \( \phi : R \rightarrow S \) is an isomorphism such that \( \phi(I) = J \), then the mapping

\[
\bar{\phi} : R/I \rightarrow S/J, x + I \mapsto \phi(x) + J
\]

is well-defined and is an isomorphism.

Proof Left to the reader. \[ \square \]

If \( F \) and \( F' \) are fields and \( \sigma : F \rightarrow F' \) is an isomorphism, then by setting

\[
\sigma^*(\sum a_iX^i) = \sum \sigma(a_i)X^i
\]

we obtain an isomorphism from the ring \( F[X] \) onto the ring \( F'[X] \). We will say that \( \sigma^* \) corresponds to \( \sigma \). We will often write \( f^* \) for \( \sigma^*(f) \).
Proposition 2.3 Let \( \sigma : F \rightarrow F' \) be an isomorphism and \( f \in F[X] \) irreducible. If \( E \) (resp. \( E' \)) is an extension of \( F \) (resp. \( F' \)) and \( \alpha \) (resp. \( \alpha' \)) a root of \( f \) (resp. \( f' \)) in \( E \) (resp. \( E' \)), then there is an isomorphism \( \tilde{\sigma} : F(\alpha) \rightarrow F'(\alpha') \) extending \( \sigma \), with \( \tilde{\sigma}(\alpha) = \alpha' \). This isomorphism is unique.

Proof First we notice that \( \sigma^*(f) = (f^*) \); from the preceding lemma the mapping

\[
\tilde{\sigma}^* : F[X] / (f) \rightarrow F'[X] / (f'), g + (f) \mapsto \sigma^*(g) + (f')
\]

is an isomorphism. We now set \( \tilde{\sigma} \) as the composition

\[
F(\alpha) \xrightarrow{\phi^{-1}} F[X] / (f) \xrightarrow{\tilde{\sigma}^*} F'[X] / (f') \xrightarrow{\phi'} F'(\alpha').
\]

\( \tilde{\sigma} \) is an isomorphism extending \( \sigma \) and \( \tilde{\sigma}(\alpha) = \alpha' \). The uniqueness is clear. \( \square \)

We are now in a position to prove the result referred to above, namely that splitting fields are isomorphic. We will in fact prove a more general result and derive that on splitting fields as a corollary.

Theorem 2.2 Let \( F \) and \( F' \) be fields, \( \sigma : F \rightarrow F' \) an isomorphism, \( f \in F[X] \) and \( f^* \in F'[X] \) the polynomial corresponding to \( f \). If \( E \) is a splitting field of \( f \) and \( E' \) a splitting field of \( f^* \), then there is an isomorphism \( \tilde{\sigma} : E \rightarrow E' \) extending \( \sigma \).

Proof We will prove this result by recurrence on \( n = [E : F] \). First, if \( n = 1 \), then \( E = F \) and \( f \in F[X] \) and \( f^* \) is a product of linear factors (polynomials of degree 1) and it follows that \( f^* \) is also a product of such factors, so \( E' = F' \) and we can define \( \tilde{\sigma} = \sigma \).

Now let us suppose that \( n > 1 \) and that the result is true up to \( n - 1 \). Let \( g \) be an irreducible factor of \( f \) with \( \deg g \geq 2 \) and \( \alpha \) a root of \( g \) in \( E \) (\( \alpha \in E \) because \( \alpha \) is a root of \( f \)). Let \( g^* \) be the polynomial in \( F'^*[X] \) corresponding to \( g \) and \( \alpha' \) a root of \( g^* \) (\( \alpha' \in E' \) because \( \alpha' \) is a root of \( f^* \)). From Proposition 2.3 there is a unique isomorphism \( \tilde{\sigma} : F(\alpha) \rightarrow F'(\alpha') \) which extends \( \sigma \) and is such that \( \tilde{\sigma}(\alpha) = \alpha' \). Now, \( E \) is a splitting field of \( f \) over \( F(\alpha) \) and \( E' \) a splitting field of \( f^* \) over \( F'(\alpha') \). As

\[
[E : F] = [E : F(\alpha)] [F(\alpha) : F]
\]

and \( [F(\alpha) : F] \geq 2 \), we have \( [E : F(\alpha)] < n \). By the induction hypothesis there is an isomorphism \( \tilde{\sigma} : E \rightarrow E' \), which extends \( \tilde{\sigma} \), and hence \( \sigma \). \( \square \)

Corollary 2.2 If \( f \in F[X] \) and \( E \) and \( E' \) are splitting fields of \( f \) over \( F \), then \( E \) and \( E' \) are isomorphic.

Proof It is sufficient to take \( F' = F \) and \( \sigma = \text{id}_F \) in the previous theorem. \( \square \)

Example Let \( f(X) = -2 + X^3 \in Q[X] \). The roots of \( f \) in \( C \) are \( \alpha_1 = \sqrt[3]{2} \in R \), \( \alpha_2 = \alpha_1(-\frac{1}{2} + \frac{\sqrt{3}}{2}) \) and \( \alpha_3 = \frac{1}{2} - \frac{\sqrt{3}}{2} \). As none of the roots belong to \( Q \), \( f \) is irreducible. As \( f \) is also monic \( f \) is the minimal polynomial of \( \alpha_1 \) and so \([Q(\alpha_1) : Q] = 3 \). The field \( Q(\alpha_1) \) cannot be the splitting field in \( C \) of \( f \), because \( Q(\alpha_1) \subset R \) and \( \alpha_2 \not\in R \). The field \( K = Q(\alpha_1, \sqrt{3}) \subset Q(\alpha_1, \alpha_2, \alpha_3) \); as \( \alpha_1, \alpha_2, \alpha_3 \) belong to \( Q \) lie in \( K \), we have \( K = Q(\alpha_1, \alpha_2, \alpha_3) \), i.e., \( K \) is the splitting field of \( f \) in \( C \).

We only need to find the degree of the extension. From Theorem 2.1 we know that it cannot be greater than \( 3! = 6 \). It also must be a multiple of 3, because

\[
[K : Q] = [K : Q(\alpha_1)][Q(\alpha_1) : Q] = [K : Q(\alpha_1)]3.
\]

If \([K : Q] = 3 \), then \([K : Q(\alpha_1)] = 1 \) and \( K = Q(\alpha_1) \), which is false; hence \([K : Q] = 6 \).
**Exercise 2.1** Find the splitting field $K$ of $f(X) = 4 - 2X + X^2 \in \mathbb{Q}[X]$ in $\mathbb{C}$ and determine the degree of the extension of $K$ over $\mathbb{Q}$.

**Exercise 2.2** Let $C$ be a family of polynomials in $F[X]$ and $K$ an extension of $F$ such that every $f$ in $C$ splits over $K$; if, for every proper subfield $K'$ of $K$, at least one member of $C$ does not split over $K'$, then we say that $K$ is a splitting field of $C$. Show that, $C$ is finite and $K$ is a splitting field of $C$, then there is a polynomial $f \in F[X]$ for which $K$ is a splitting field.

### 2.1 Existence of finite fields

We recall that we previously saw that the cardinal of a finite field must be $p^k$, where $p$ is a prime number and $k$ a positive integer. In this section we show that, for any such $p^k$, there is a finite field $F$ whose cardinal is precisely $p^k$, and that, in addition, there is essentially only one such finite field. We will use our knowledge of splitting fields in the proofs. We begin with a preliminary result, but for this we need a lemma.

**Lemma 2.3** Let $f, g \in F[X]$ be nonconstant. Then $f$ and $g$ are relatively prime if and only if they do not have a root in any extension field of $F$.

**Proof** Assume that $f$ and $g$ are relatively prime in $F[X]$. Then there exist $u, v \in F[X]$ such that

$$f(X)u(X) + g(X)v(X) = 1.$$ 

If $\alpha$ is a common root of $f$ and $g$ in some field extension of $F$, then substituting $\alpha$ for $X$ we obtain 0 on the left-hand side and 1 on the right-hand side of the equation, a contradiction. Hence $f$ and $g$ have no common root in an extension field of $F$.

Now suppose that $f$ and $g$ are not relatively prime. Then $f$ and $g$ have a common factor $h$, which is not a constant. There is a field extension of $F$ in which $h$ has a root $\alpha$. Clearly, $\alpha$ is a common root of $f$ and $g$. 

**Proposition 2.4** If $f \in F[X]$, then $f$ has a multiple root in a splitting field if and only if $\gcd(f, f') \neq 1$.

**Proof** Suppose that $f$ has a multiple root $\alpha$ in a splitting field. Then $f(X) = (X - \alpha)^sg(X)$, where $s \geq 2$ and $g(\alpha) \neq 0$. Hence,

$$f'(X) = s(X - \alpha)^{s-1}g(X) + (X - \alpha)^sg'(X)$$

and so $f'(\alpha) = 0$. From the previous lemma $f$ and $f'$ are not relatively prime, i.e., $\gcd(f, f') \neq 1$.

Now suppose that $\gcd(f, f') \neq 1$. From the previous lemma, $f$ and $f'$ have a common root $\alpha$ in an extension field of $F$. We may write

$$f(X) = (X - \alpha)^sg(X),$$

with $s \geq 1$ and $g(\alpha) \neq 0$. Then again

$$f'(X) = s(X - \alpha)^{s-1}g(X) + (X - \alpha)^sg'(X).$$

If $s = 1$, then $f'(\alpha) = g(\alpha) \neq 0$, a contradiction, hence $s \geq 2$ and $\alpha$ is a multiple root. 

**Theorem 2.3** If $p$ is a prime number and $k$ a positive integer, then there is a field $F$ whose cardinal is $p^k$. 

19
We take a set of roots. We claim that \( k > q \) roots (Proposition 2.4). Let \( E \) be an extension of \( \mathbb{F}_p \) which contains the roots of \( f \) and \( F \) the set of roots. We claim that \( F \) is a field. First, if \( a \in F \), then

\[
0 = f(a) = -a + a^q \iff x = x^q.
\]

We take \( x, y \in F \). Then

\[
(xy)^q = x^qy^q = xy \implies f(xy) = 0 \quad \text{and} \quad (x + y)^q = x^q + y^q = x + y \implies f(x + y) = 0.
\]

If \( p \neq 2 \), then

\[
(-x)^q = (-1)^q x^q = -x
\]

and, if \( p = 2 \), then

\[
(-x)^q = (-1)^q x^q = x^q = x = -x,
\]

because the characteristic of \( E \) is 2. In both cases we have \( f(-x) = -x \). It follows that \( F \) is a subring of \( E \). In addition, if \( x \neq 0 \), then, using the fact that \( F \) is an integral domain, we have

\[
-x + x^q = 0 \implies -1 + x^q = 0 \implies x^q - 1 = 1,
\]

hence \( x \) has an inverse for the multiplication. Thus \( F \) is a field. We have constructed a field with \( q = p^k \) elements.

We now turn to the uniqueness of finite fields. We should notice that the field \( F \) constructed in the proof of preceding theorem is a splitting field for the polynomial \( f \). Any proper subfield of \( F \) will lack certain elements of \( F \). As these are all roots of \( f \), \( f \) cannot split over such a subfield.

**Theorem 2.4** If \( F \) and \( F' \) are two finite fields with the same cardinality, then \( F \) is isomorphic to \( F' \).

**Proof** If \( F \) is a finite field with cardinality \( q = p^k \), then \( F \) has the prime field \( \mathbb{F}_p \). There \( q - 1 \) elements in \( F^* \), so, if \( x \in F^* \), then \( x^{q-1} = 1 \) and it follows that \( -x + x^q = 0 \), for all \( x \in F \). Thus the roots of the polynomial \( f(X) = X + X^q \in \mathbb{F}_p[X] \) are the elements of \( F \) and it follows that \( F \) is a splitting field of \( f \). As all splitting fields of a given polynomial are isomorphic, if \( F' \) is another field with cardinality \( q \), then \( F' \) is isomorphic to \( F \).

**Notation** We often write \( \mathbb{F}_q \) for a finite field with \( q \) elements.

## 2.2 Algebraic closures

We have seen that if \( f \in F[X] \) then there is an extension \( E \) of \( F \) over which \( f \) splits. It is natural to ask if there exists an extension \( C \) of \( F \) such that every \( f \in F[X] \) splits over this extension. (It is well-known that \( \mathbb{C} \) is such an extension of \( \mathbb{R} \), however, we will give a proof of this later on in the text.) In this section we aim to study this question. We will begin with an elementary result.

**Proposition 2.5** For a field \( C \) the following conditions are equivalent

- **a.** Every nonconstant polynomial \( f \in C[X] \) has a root \( \alpha \in C \);
• b. Every nonconstant polynomial $f \in C[X]$ splits over $C$;
• c. Every irreducible polynomial $f \in C[X]$ is of degree 1;
• d. $C$ has no proper algebraic extension.

Proof a. $\implies$ b. If $f$ is nonconstant, then the condition a. implies that we can write $f(X) = (X - \alpha)g(X)$. If $g$ is not constant, then we can write $g(X) = (X - \beta)h(X)$. Continuing the process if necessary we finally obtain a splitting of $f$.

b. $\implies$ c. If $f$ is irreducible, then $f$ is not constant. From the condition b. $f$ splits over $C$:

$$f(X) = \lambda(X - \alpha_1) \cdots (X - \alpha_n).$$

As $f$ is irreducible, $f$ has a unique nonconstant facteur, i.e., $n = 1$.

c. $\implies$ d. Let $E$ be an algebraic extension of $C$ and $\alpha \in E$. If $f = m(\alpha, C)$, then $f$ is irreducible and so of degree 1: $f(X) = X - \alpha$. Hence $\alpha \in C$. Thus $E = C$.

d. $\implies$ a. Let $f \in C[X]$ nonconstant. We can find an extension $E$ of $C$ which contains a root $\alpha$ of $f$. We may suppose that this extension is finite and so algebraic. From the condition d., $E = C$ and so $\alpha \in C$.

A field satisfying the conditions of the above proposition is said to be algebraically closed. An extension $C$ of a field $F$ is an algebraic closure of $F$ if $C$ is algebraic over $F$ and algebraically closed.

Remark An algebraically closed field is infinite. To see this, suppose that $F$ is algebraically closed and finite, with elements $\alpha_1, \ldots, \alpha_n$. However, the polynomial $f(X) = 1 + \prod_{i=1}^{n}(-\alpha_i + X)$ has no root in $F$, contradicting the fact that $F$ is algebraically closed.

Exercise 2.3 If $E$ is an algebraic extension of $F$ and $C$ an algebraic closure of $E$, show that $C$ is an algebraic closure of $F$.

Remark If $C$ is an algebraic closure of $F$ and $E$ is an extension of $F$ which is strictly included in $C$, then $E$ is not algebraically closed. To see this, let $\alpha \in C \setminus E$. As $\alpha$ is algebraic over $F$, $\alpha$ is algebraic over $E$. Now, $\alpha \notin E$, hence $\deg m(\alpha, E) > 1$; from the condition c. of the above proposition, $E$ is not algebraically closed.

Proposition 2.6 Let $C$ be an algebraic extension of $F$. Then $C$ is an algebraic closure of $F$ if every nonconstant polynomial $g \in F[X]$ splits over $C$. (We do not need to consider polynomials $f \in C[X] \setminus F[X]$).

Proof Let $f \in F[X]$ and $\alpha$ be a root of $f$ in an extension $E$ of $C$. The field $C(\alpha)$ is an algebraic extension of $F$ and $C$ is algebraic over $F$ by hypothesis, therefore $C(\alpha)$ is algebraic $F$. Thus $\alpha$ is the root of a polynomial $g \in F[X]$. As $g$ splits over $C$, all the roots of $g$ belong to $C$; in particular $\alpha \in C$. Thus $f$ has a root in $C$.

If $E$ and $E'$ are extensions of $F$ and $\sigma : E \longrightarrow E'$ is a homomorphism fixing $F$ (i.e., $\sigma(x) = x$, for all $x \in F$), then we call $\sigma$ an $F$–homomorphism. The following proposition is well-known if $E$ is a finite extension of $F$. However, we may relax the conditions:

Proposition 2.7 Let $E$ be an algebraic extension of $F$ and $\sigma : E \longrightarrow E$ an $F$-homomorphism. If $\sigma$ is injective, then it is also surjective.
PROOF Let $\alpha \in E$. We have to show that there exists $\beta \in E$ such that $\alpha = \sigma(\beta)$. Let $m = m(\alpha, F)$ and $L$ be the subfield of $E$ generated by $F$ and the roots of $m$ which are in $E$. These roots are algebraic over $F$, therefore $L$ is a finite extension of $F$ (see Corollary 1.5). If $\alpha'$ is a root of $m$ in $E$, then $\sigma(\alpha')$ is also a root of $m$ in $E$, because $\sigma$ is an $F$-homomorphism and so $\sigma(L) \subset L$. However, $\sigma$ is a linear mapping from the $F$-vector space $L$ into itself, because $F$ is fixed by $\sigma$. As $L$ is finite-dimensional over $F$ and $\sigma$ injective, $\sigma|_L : L \rightarrow L$ is also surjective. Moreover, $\alpha \in L$, thus there exists $\beta \in L \subset E$ such that $\alpha = \sigma(\beta)$.

We now prove the most difficult step in showing that a field always has an algebraic closure.

**Theorem 2.5** Every field $F$ has an extension $E$ which is algebraically closed.

**PROOF** We note $S$ the collection of nonconstant polynomials of $F[X]$. To each $f \in S$ we associate a variable $X_f$. Now let $T$ be the family of these variables and $F[T]$ the ring of polynomials in these variables. (The elements of $F[T]$ are finite sums of monomials of the form $aX_{f_1}\cdots X_{f_s}$, with $a \in F$.) Finally we define $I$ to be the ideal generated by the elements of the form $f(X_f)$, with $f \in S$. (If $f(X) = \sum_{i=0}^{n} a_i X_i$, then $f(X_f) = \sum_{i=0}^{n} a_i X_{f_i}$.) In fact, $I$ is a proper ideal of $F[T]$ as we will now see. If this is not the case, then we can find elements $g_i \in F[T]$ and $f_i \in I$ such that

$$\sum_{i=1}^{s} g_i f_i = 1.$$ 

Let us write $X_i$ for the variable associated with $f_i$. There is a finite number of variables $X_1, \ldots, X_m$ with $m \geq s$, which are variables of the $g_i$. Hence we have

$$\sum_{i=1}^{s} g_i(X_1, \ldots, X_m)f_i(X_i) = 1.$$ 

(Even if a certain variable $X_k$ does not appear explicitly in a certain $g_i$, we can still include it.) Suppose now that $E$ is an extension of $F$ which contains all the roots of the $f_i$. Then $E$ contains a root $\alpha_i$ of each $f_i$. If we set $X_i = \alpha_i$ for $1 \leq i \leq s$ and $X_i = 0$ for $s < i \leq m$, then we obtain $0 = 1$, a contradiction. It follows that $I$ is a proper ideal of $F[T]$.

As $I$ is a proper ideal, $I$ is included in a maximal ideal $M$. The factor ring $E_1 = F[T]/M$ is a field, because $M$ is maximal. The canonical homomorphism

$$\phi : F \rightarrow E_1, a \mapsto a + M$$

is injective: If $\phi(a) = 0$ and $a \neq 0$, then $a + M = M$ and

$$(a^{-1} + M)(a + M) \subset M \implies 1 \in M,$$

a contradiction. Hence we can write $F \subset E_1$. If $f \in F[X]$ is nonconstant, then $X_f \in E_1$ and

$$f(X_f + M) = f(X_f) + M = 0,$$

because $f(X_f) \in I \subset M$. Therefore $f$ has a root in $E_1$.

We can now replace $F$ by $E_1$ and repeat the whole argument to obtain an extension $E_2$ of $E_1$ such that every nonconstant polynomial $g \in E_1[X]$ has a root in $E_2$. Continuing in the same way we obtain a chain of extensions

$$F \subset E_1 \subset E_2 \subset \cdots$$
such that a nonconstant polynomial $h \in E_n[X]$ has a root in $E_{n+1}$. We now let $E$ be the union of the fields in the chain and we define an addition $\oplus$ and a multiplication $\circ$ on $E$ as follows: If $x \in E_m$ and $y \in E_n$, with $m \leq n$, then $x \oplus y = x +_n y$ and $x \circ y = x \cdot_n y$. These operations are well-defined ($x \oplus y$ and $x \circ y$ do not depend on the choice of $n \geq m$) and a simple check shows that \((E, \oplus, \circ)\) is a field.

Now let $f$ be a nonconstant polynomial in $E[X]$. All the coefficients of $f$ belong to a certain $E_n$ and so $f$ has a root in $E_{n+1} \subset E$. Thus we have an extension of $F$ which is algebraically closed. \hfill \qed

We may now prove the principal result of this section.

**Theorem 2.6** Every field $F$ has an algebraic closure.

**Proof** From the previous theorem, $F$ has an extension $E$ which is algebraically closed. Let $G = A(E/F)$, i.e., the collection of elements of $E$ which are algebraic over $F$. Proposition 1.6 ensures us that $G$ is a subfield of $E$. Let us take $f \in G[X]$ nonconstant. As $f \in E[X]$, $f$ has a root $\alpha \in E$. As $f \in G[X]$, $\alpha$ is algebraic over $G$. Now, $G$ is an algebraic extension of $F$ and $\alpha$ is algebraic over $G$, therefore $\alpha$ is algebraic over $F$, by Proposition 1.7. It follows that $\alpha \in G$. We have shown that $G$ is algebraically closed. \hfill \qed

**Remark** The previous proof shows that the field of algebraic numbers $A(C/Q)$ is an algebraic closure of $Q$. Moreover, the remark after Proposition 1.6 and Theorem 1.5 ensures that $A(C/Q)$ is a countable infinite extension of $Q$.

**Exercise 2.4** Show that $C$ is an algebraic closure of $R$.

We have shown that a field always has an algebraic closure. Our next task is to show that any two such closures are isomorphic.

**Lemma 2.4** Let $\sigma$ be a monomorphism from a field $F$ into an algebraically closed field $C$. If $E$ is an extension of $F$, $\alpha \in E$ algebraic over $F$, then $\sigma$ can be extended to a monomorphism from $F(\alpha)$ into $C$.

**Proof** Let $F' = \sigma(F)$ and $f = m(\alpha, F)$. If $f^\ast$ is the polynomial corresponding to $f$ in $F'[X]$, then $f^\ast$ has a root $\alpha' \in C$. Applying Proposition 2.3 we see that there is an isomorphism $\tilde{\sigma}$ from $F(\alpha)$ onto $F'(\alpha')$. As $F'(\alpha') \subset C$ we have a monomorphism from $F(\alpha)$ into $C$ extending $\sigma$. \hfill \qed

**Theorem 2.7** If $\sigma : F \rightarrow C$ is a monomorphism, with $C$ algebraically closed, and $E$ an algebraic extension of $F$, then $\sigma$ may be extended to a monomorphism $\tilde{\sigma} : E \rightarrow C$.

**Proof** Let $G$ be the collection of all pairs $(K, \mu)$, where $K/F$, $E/K$ and $\mu$ is a monomorphic extension of $\sigma$ to $K$. (From the previous lemma, such pairs exist.) We now order these pairs: $(K_1, \mu_1) \leq (K_2, \mu_2)$ if and only if $K_1 \subset K_2$ and $\mu_2$ restricted to $K_1$ is equal to $\mu_1$. If the pairs $(K_i, \mu_i)$ form a chain $Q$, then $Q$ has a maximum $(K, \mu)$, with $K = \cup K_i$ and $\mu(x) = \mu_i(x)$, if $x \in K_i$. From Zorn’s lemma, $G$ has a maximal element $(K_0, \mu_0)$. We claim that $K_0 = E$. If $K_0 \neq E$ and $\alpha \in E \setminus K_0$, then from the previous lemma, we may extend $\mu_0$ to a monomorphism from $K_0(\alpha)$ into $C$. However, this contradicts the maximality of the pair $(K_0, \mu_0)$. Hence $K_0 = E$; This finishes the proof. \hfill \qed

If we add some conditions we obtain the important following corollary:
**Corollary 2.3** If, in the above theorem, $E$ is algebraically closed and $C$ algebraic over $\sigma(F)$, then $\hat{\sigma}$ is an isomorphism.

**Proof** We only need to show that $\hat{\sigma}(E) = C$. As $C$ is algebraic over $\sigma(F)$, $C$ is algebraic over $\hat{\sigma}(E)$, because $\sigma(F)$ is a subset of $\hat{\sigma}(E)$. Now, $\hat{\sigma}(E)$ is algebraically closed, because $E$ is algebraically closed, hence $C$ is an algebraic extension of the algebraically closed field $\hat{\sigma}(E)$. From Proposition 2.5 d., $C$ cannot be a proper extension and so $\hat{\sigma}(E) = C$. \hfill $\Box$

We can now prove that the following theorem holds:

**Theorem 2.8** If $C_1$ and $C_2$ are algebraic closures of the field $F$, then $C_1$ and $C_2$ are $F$-isomorphic.

**Proof** $F$ is a subfield of $C_1$ and $C_2$. If $\sigma : F \rightarrow C_2$ is the inclusion mapping, then, from the previous corollary, we may extend $\sigma$ to an isomorphism $\hat{\sigma} : C_1 \rightarrow C_2$. This clearly fixes $F$. \hfill $\Box$

**Exercise 2.5** Let $F$ be any field. Show that there is an infinite number of irreducible elements in the polynomial ring $F[X]$. Deduce that if $F$ is algebraically closed, then $F$ is infinite.
Chapter 3

Separability

In this chapter we aim to look at two related topics, namely separable polynomials and separable extensions. We will begin with the first subject.

3.1 Separable polynomials

Let $f \in F[X]$ be nonconstant with the factorization into irreducible elements

$$f(X) = \lambda g_1(X) \cdots g_n(X).$$

If each $g_i$ has no multiple root in a splitting field, then we say that $f$ is separable. We will say that a polynomial is strongly separable, if it has no multiple roots. Clearly, a strongly separable polynomial is separable, but a separable polynomial is not necessarily strongly separable. For example, $f(X) = (X^2 + 1)^2 \in \mathbb{Q}[X]$ is separable, but not strongly separable. However, for an irreducible polynomial these notions are equivalent: If $f \in F[X]$ is irreducible, then $f$ is separable if and only if $f$ is strongly separable.

Proposition 2.4 is useful in determining whether a polynomial is separable or not. Consider a polynomial $f \in F[X]$. If $\gcd(f, f') = 1$, then $f$ has no multiple root and so this is the case for any factor; it follows that $f$ is strongly separable and hence separable. On the other hand, if $\gcd(f, f') \neq 1$, then $f$ is not strongly separable; however, $f$ may be separable or not. We must consider the irreducible factors of $f$.

**Corollary 3.1** If the characteristic of the field $F$ is 0, then every polynomial $f \in F[X]$ is separable.

**Proof** Let $g$ be an irreducible factor of $f$. As the characteristic of $F$ is 0, $g' \neq 0$. If $h = \gcd(g, g')$, then $\deg h < \deg g$, because $\deg g' < \deg g$. As $g$ is irreducible, $h = 1$. From the preceding proposition, $g$ has no multiple root. $\square$

Now we consider finite fields. If $F$ is such a field, then its characteristic is a prime number $p$. Let $f \in F[X]$. If, for every irreducible factor $g$ of $f$, $g' \neq 0$, then, using the argument of the corollary we have just proved, $f$ is separable. We claim that this is always the case. Suppose that this is not the case and let $g$ be an irreducible factor of $f$ with $g' = 0$. Then $g \in F[X^p]$. The mapping

$$\phi : F \rightarrow F : x \mapsto x^p$$

25
which implies that \( \text{Ker } \phi \) is a homomorphism: 
\[
\phi(xy) = (xy)^p = x^p y^p = \phi(x)\phi(y)
\]
\[
\phi(x + y) = (x + y)^p = \sum_{i=0}^{p} \binom{p}{i} x^i y^{p-i} = x^p + y^p = \phi(x) + \phi(y).
\]
(We have used the fact that \( p \) divides \( \binom{p}{i} \) if \( 1 \leq i \leq p - 1 \).) As \( F \) is a field and \( \text{Ker } \phi \) is an ideal 

\[ \text{Ker } \phi = \{0\} \text{ or } \text{Ker } \phi = F. \]

As \( \phi(1) = 1 \), the second alternative is not possible, so \( \text{Ker } \phi = \{0\} \), which implies that \( \phi \) is injective. Given that \( F \) is finite, \( \phi \) must also be surjective. Now let us return to \( g \). We may write 

\[ g(X) = \sum_{i=0}^{k} a_i X^{ip}. \]

As \( \phi \) is bijective, for each \( a_i \), there exists \( b_i \) such that \( a_i = b_i^p \). We have 

\[ g(X) = \sum_{i=0}^{k} b_i^p X^{ip} = \left( \sum_{i=0}^{k} b_i X^{i} \right)^p, \]

a contradiction to the irreducibility of \( g \). Hence \( g' \neq 0 \) and we have proven

**Proposition 3.1** If \( F \) is a finite field, then every polynomial \( f \in F[X] \) is separable.

**Remark** Corollary 3.1 and Proposition 3.1 imply that if \( \text{char } F = 0 \) or \( F \) is finite, then an irreducible polynomial \( f \in F[X] \) is strongly separable.

Although polynomials which are not separable are relatively rare, such polynomials exist. Here we will give an example. We recall Eisenstein’s criterion:

Let \( R \) be a unique factorization domain, with quotient field \( F \), and 

\[ f(X) = \sum_{i=0}^{n} a_i X^i \in R[X], \]

with \( \deg f \geq 1 \). If \( q \) is prime in \( R \) and \( q \) divides \( a_i \), for \( 0 \leq i < n \), \( q \) does not divide \( a_0 \) and \( q^2 \) does not divide \( a_0 \), then \( f \) is irreducible in \( R[X] \).

Consider \( F_p(t) \), the field of rational fractions over the field \( F_p \), for any given prime \( p \). The characteristic of \( F_p(t) \) is \( p \). We note \( f(X) = X^p - t \in F_p[t][X] \). If \( q(t) \) is prime in \( F_p[t] \), then \( \deg q^2 \geq 2 \) and so \( q^2 \) does not divide \( t \); it follows from Eisenstein’s criterion that \( f \) is irreducible. We claim that \( f \) has a multiple root in a splitting field. Let \( \alpha \) be a root of \( f \) in a splitting field and suppose that 

\[ f(X) = (X - \alpha)^m g(X), \]

where \( \deg g \geq 1 \) and \( g(\alpha) \neq 0 \). Then 

\[ 0 = f'(X) = m(X - \alpha)^{m-1} g(X) + (X - \alpha)^m g'(X). \]

This implies that \( mg(X) = -(X - \alpha)g'(X) \) and so \( mg(\alpha) = 0 \). However, this is impossible, because \( m < p \) and \( g(\alpha) \neq 0 \). Therefore, \( f(X) = (X - \alpha)^p \) and \( f \) is not separable.

In Theorem 2.2 we showed that an isomorphism \( \sigma \) from the field \( F \) onto the field \( F' \) may be extended to an isomorphism \( \tilde{\sigma} : E \rightarrow E' \), where \( E \) is a splitting field of \( f \in F[X] \) and \( E' \) a splitting field of \( f' \), the polynomial in \( F'[X] \) corresponding to \( f \). If \( f \) is separable, then we can say a little more.

**Theorem 3.1** If \( f \) is separable, then \( \sigma \) can be extended to \( E \) in exactly \( [E : F] \) distinct ways.
3.2 Separable extensions

If $E$ is an extension of $F$ and $\alpha \in E$, then $\alpha$ is a separable element over $F$, if $\alpha$ is algebraic over $F$ and the minimal polynomial $m(\alpha, F)$ is separable. If every element $\alpha \in E$ is separable, then we say that $E$ is a separable extension of $F$. From Corollary 3.1 and Proposition 3.1 we know that every algebraic extension of a field of characteristic 0 or of a finite field is separable.

We have seen in Theorem 2.7 that if $\sigma : F \rightarrow C$ is a monomorphism, with $C$ algebraically closed, and $E$ an algebraic extension of $F$, then $\sigma$ may be extended to a monomorphism $\hat{\sigma} : E \rightarrow C$. If $E$ is a finite separable extension of $F$ then we can say a little more.

**Theorem 3.2** Let $E$ be a finite separable extension of $F$, with $[E : F] = n$, and $\sigma$ a monomorphism from $F$ into $C$, which is algebraically closed. Then there are exactly $n$ monomorphic extensions $\hat{\sigma} : E \rightarrow C$ of $\sigma$.

**Proof** We will prove this result by induction on $n$. If $n = 1$ then $E = F$ and there is nothing to prove. Suppose now that $n > 1$ and that the result is correct up to $n - 1$. Let $\alpha \in E \setminus F$, $m = m(\alpha, F)$ and $m^*$ be the polynomial in $K[X]$ corresponding to $m$, where $K = \sigma(F)$. As $m$ is separable, so is $m^*$. Given that $C$ is algebraically closed, $m^*$ has a root $\alpha' \in C$ and there is a unique isomorphism $\hat{\sigma} : F(\alpha) \rightarrow K(\alpha')$ extending $\sigma$ and such that $\hat{\sigma}(\alpha) = \alpha'$ (Proposition 2.3). If $\deg m = d$, then

$$[F(\alpha) : F] = d \implies [E : F(\alpha)] = \frac{n}{d} < n.$$  

Also $\deg m^* = d$, so $m^*$ has $d$ distinct roots in $C$, because it is separable. Thus we have $d$ choices for $\alpha'$, and thus for $\hat{\sigma}$, and, by the induction hypothesis, each mapping $\hat{\sigma} : F(\alpha) \rightarrow K(\alpha')$ can be extended to a monomorphism from $E$ into $C$ in $\frac{n}{d}$ ways. We thus obtain $\frac{n}{d}d = n$ monomorphisms $\hat{\sigma}$ from $E$ into $C$ extending $\sigma$.

It is not difficult to see that there can be no more than $n$ such extensions. If $\tau$ is such an extension, then $\alpha' = \tau(\alpha)$ is a root of $m^*$ and $\tau$ restricted to $F(\alpha)$ is an isomorphism onto $F(\alpha')$. The mapping $\tau$ is then a monomorphic extension of this restriction and so is one of the mappings we have already considered. \hfill \Box

**Corollary 3.2** If $E$ is a finite separable extension of $F$, with $[E : F] = n$, and $C$ an algebraically closed extension of $F$, then there are exactly $n$ $F$-monomorphisms of $E$ into $C$.  

27
Finite separable extensions have a useful property which Theorem 3.2 enables us to prove. We will also need an elementary result on finite fields, which is interesting in itself, namely that the multiplicative group of nonzero elements of a finite field is cyclic. We will prove a more general result. We recall that Euler’s totient function \( \phi \) is defined on \( \mathbb{N}^* \) as follows: \( \phi(n) \) is the number of elements in the set \( \{d : 1 \leq d \leq n, (d,n) = 1\} \). We have the following identity \( \sum_{d|n} \phi(d) = n \).

**Theorem 3.3** If \( F \) is a field and \( G \) a finite subgroup of the multiplicative group \( F^* \), then \( G \) is cyclic.

**Proof** We set \( |G| = n \). If \( x \in G \), then \( o(x) \) is the order of the element \( x \). For each divisor \( d \) of \( n \), let us write \( \psi(d) \) for the number of elements in \( G \) whose order is \( d \). If \( \psi(d) \neq 0 \), then there is an element \( x \in G \) whose order is \( d \). If \( y \in H \), the group generated by \( x \), then \( y^d = 1 \), hence \( y \) is a root of the polynomial \( f(X) = -1 + X^d \in F[X] \). As \( f \) has at most \( d \) roots and \( H \) has \( d \) elements, all the roots of \( f \) are in \( H \), in particular, any element of order \( d \) is in \( H \). Also, the elements of order \( d \) in \( H \) are the generators of this group and there are \( \phi(d) \) such generators, hence we have \( \psi(d) = \phi(d) \). If \( \psi(d) = 0 \), for a certain divisor \( d \) of \( n \), then we have

\[
\psi(d) < \phi(d) = n,
\]

a contradiction. It follows that \( \psi(d) = \phi(d) \) for every divisor \( d \) of \( n \). In particular, \( \psi(n) = \phi(n) \geq 1 \) and so \( G \) is cyclic. \( \square \)

**Corollary 3.3** If \( F \) is a finite field, then its group of nonzero elements is cyclic.

We may now prove the interesting result we referred to above.

**Theorem 3.4** (primitive element theorem) If \( E \) is a finite separable extension of \( F \), then there exists an element \( \alpha \in E \), such that \( E = F(\alpha) \).

**Proof** If \( E \) is finite, then so is \( E \), being a finite extension. If \( \alpha \) is a generator of the cyclic group \( E^* \), then \( E = F(\alpha) \).

Now let us consider the case where \( F \) is not finite. We will use an argument by induction on \( [E : F] = n \). If \( n = 1 \), then \( E = F \) and we can take any element \( \alpha \in F \). Now let us suppose that \( n > 1 \) and that the result is true up to \( n - 1 \). We take \( \alpha \in E \setminus F \). We claim that \( E \) is a separable extension of \( F(\alpha) \). To see this, notice that, if \( \gamma \in E \), then \( \gamma \) is algebraic over \( F \), hence algebraic over \( F(\alpha) \); in addition, \( m(\gamma, F(\alpha)) | m(\gamma, F) \), thus, if \( m(\gamma, F(\alpha)) \) has a multiple root, then so does \( m(\gamma, F) \), a contradiction. This proves the claim.

By hypothesis there is a \( \beta \in E \) such that \( E = F(\alpha, \beta) \). We will now show that there is an element \( c \in F \) such that \( E = F(\alpha + c\beta) \). From Corollary 3.2 we know that there are exactly \( n \) \( F \)-monomorphisms of \( E \) into an algebraic closure \( C \) of \( F \). For any \( c \in F \), each one of these mappings restricted to \( F(\alpha + c\beta) \) is clearly an \( F \)-monomorphism into \( C \). If \( F(\alpha + c\beta) \neq E \), then \( [F(\alpha + c\beta) : F] < n \) and so there are distinct \( F \)-monomorphisms \( \sigma \) and \( \tau \) of \( E \) into \( C \) which coincide on \( F(\alpha + c\beta) \). We have

\[
\sigma(\alpha) + c\sigma(\beta) = \tau(\alpha) + c\tau(\beta).
\]
If $\sigma(\beta) = \tau(\beta)$, then also $\sigma(\alpha) = \tau(\alpha)$, which implies that $\sigma = \tau$, because $E = F(\alpha, \beta)$. This is a contradiction and so $\sigma(\beta) \neq \tau(\beta)$ and we can write
\[
c = \frac{\sigma(\alpha) - \tau(\alpha)}{\tau(\beta) - \sigma(\beta)}.
\]
However, a little reflexion shows that there is only a finite number of values $c$ which can be expressed in this form; therefore we can find an element $c \in F$ such that $E = F(\alpha + c\beta)$, which finishes the proof.

If $E$ is an extension of $F$ and $\alpha \in E$ is such that $E = F(\alpha)$, then we say that $\alpha$ is a primitive element, hence the name of the theorem which we have just proved. The primitive element theorem has an interesting application to quadratic number fields, namely

**Theorem 3.5** If $E$ is a quadratic number field, then there is a square-free integer $d$ such that $E = \mathbb{Q}(\sqrt{d})$.

**Proof** Let $E$ be a quadratic number field, i.e., an extension of $\mathbb{Q}$ in $\mathbb{C}$ of degree 2. As this extension is finite and separable, there is a primitive element $\alpha \in E \setminus \mathbb{Q}$, with minimal polynomial
\[
f(X) = a + bX + X^2
\]
and $a, b \in \mathbb{Q}$. As $\alpha$ is a root of $f$, we have
\[
\alpha = \frac{-b \pm \sqrt{b^2 - 4a}}{2} \implies (2\alpha + b)^2 = b^2 - 4a \in \mathbb{Q}.
\]
It is clear that $\beta = 2\alpha + b$ does not belong to $\mathbb{Q}$ and so $[\mathbb{Q}(\beta) : \mathbb{Q}] > 1$. As $[E : \mathbb{Q}] = 2$, we must have $E = \mathbb{Q}(\beta)$.

The number $\beta$ may not be a square-free integer. If $b^2 - 4a = \frac{p}{q}$, then
\[
q^2(b^2 - 4a) = p \implies (q(2\alpha + b))^2 \in \mathbb{Z}.
\]
Setting $\gamma = q(2\alpha + b)$, we have $E = \mathbb{Q}(\gamma)$ and $\gamma^2 \in \mathbb{Z}$. To finish it is sufficient to observe, as previously, that if $d = u^2v$, where $v$ is square-free, then $\mathbb{Q}(\sqrt{d}) = \mathbb{Q}(\sqrt{v})$.

Here is another application of the primitive element theorem.

**Theorem 3.6** Let $E$ be a finite separable extension of a field $F$ of degree $n$. Then the field of fractions $E(X)$ is a finite extension of degree $n$ of the field of fractions $F(X)$.

**Proof** From the primitive element theorem (Theorem 3.4), there exists $\alpha \in E$ such that
\[
E = F(\alpha) = F_{n-1}[\alpha],
\]
where $F_{n-1}[\alpha]$ is the set of polynomials of degree less than $n$ in $\alpha$ with coefficients in $F$. We set $A = \{1, \alpha, \alpha^2, \ldots, \alpha^{n-1}\}$. This set is a basis of $E$ over $F$. We will show that $A$ is also a basis of $E(X)$ over $F(X)$. First we notice that $F$, the collection of expressions of the form
\[
\frac{c_0(X)}{d_0(X)} + \frac{c_1(X)}{d_1(X)}\alpha + \cdots + \frac{c_{n-1}(X)}{d_{n-1}(X)}\alpha^{n-1},
\]

is 29
where \( \frac{c_i(X)}{d_i(X)} \in F(X) \), is a subfield of \( E(X) \). We now show that \( E(X) \subset \mathcal{F} \). If \( f \in E[X] \), then

\[
    f(X) = p_0(\alpha) + p_1(\alpha)X + \cdots + p_s(\alpha)X^s,
\]

where \( p_i(\alpha) \in F_{n-1}[\alpha] \), for \( i = 0, 1, \ldots, s \). Regrouping terms having the same power of \( \alpha \), we obtain the expression

\[
    f(X) = u_0(X) + u_1(X)\alpha + \cdots + u_{n-1}(X)\alpha^{n-1},
\]

where \( u_j \in F[X] \), for all \( j \). Hence any polynomial in \( E[X] \) lies in \( \mathcal{F} \). Now, if \( f \in E[X] \) and \( f \neq 0 \), then there exists

\[
    g(X) = \frac{c_0(X)}{d_0(X)} + \frac{c_1(X)}{d_1(X)}\alpha + \cdots + \frac{c_{n-1}(X)}{d_{n-1}(X)}\alpha^{n-1} \in \mathcal{F},
\]

such that \( fg = 1 \), because \( \mathcal{F} \) is a field. As the inverse of \( f \) in \( E(X) \) is unique, \( g \) is its inverse in \( E(X) \). It now follows that \( E(X) = \mathcal{F} \), because every element of \( E(X) \) is the product of an element of \( E[X] \) and the inverse of a nonzero element of \( E[X] \). Hence \( A \) is a generating set of \( E(X) \) over \( F(X) \).

To finish we show that the elements of \( A \) form an independent subset of \( E(X) \) over \( F(X) \). Suppose that

\[
    \frac{c_0(X)}{d_0(X)} + \frac{c_1(X)}{d_1(X)}\alpha + \cdots + \frac{c_{n-1}(X)}{d_{n-1}(X)}\alpha^{n-1} = 0,
\]

where \( \frac{c_i(X)}{d_i(X)} \in F(X) \), for all \( i \). Multiplying by the product \( d_0(X)d_1(X)\cdots d_{n-1}(X) \) we obtain

\[
    \sum_{i=0}^{n-1} c_1(X) \left( \prod_{j \neq i} d_j(X) \right) \alpha^i = 0.
\]

As the elements of \( A \) form an independent set over \( F \), they form an independent set over \( F[X] \). Because the products \( \prod_{j \neq i} d_j(X) \) are nonzero, we have

\[
    c_0(X) = c_1(X) = \cdots = c_{n-1}(X) = 0,
\]

and it follows that \( A \) is an independent set over \( F(X) \). \( \square \)

**Exercise 3.1** In the proof of Theorem 3.6 we stated that the independance of the set \( A \) over \( F \) implied its independance over \( F[X] \). Why is this so?

We have seen that an algebraic extension \( E \) of a field \( F \) may not be finite. However, in the case where \( E/F \) is separable and satisfies a certain condition, then this is the case.

**Proposition 3.2** Let \( F \) be a field and \( E \) a separable algebraic extension of \( F \). Then \( E \) is a finite extension of \( F \) if there exists \( n \in \mathbb{N}^* \) such that

\[
    \sup_{\alpha \in E} |F(\alpha) : F| \leq n.
\]

Moreover, \( |E : F| \leq n \).
PROOF Let $E$ be a separable algebraic extension of the field $F$ such that

$$\sup_{\alpha \in E} |F(\alpha) : F| \leq n.$$ 

Let $r > n$ and $\alpha_1, \ldots, \alpha_r$ elements in $E$. Then $G = F(\alpha_1, \ldots, \alpha_r) \subset E$ is a finite extension of $F$. As the $\alpha_i$ are algebraic and separable, $G$ is a separable extension of $F$ (Theorem 3.8). From the primitive element theorem, there exists $\alpha \in G$ such that $G = F(\alpha)$. As $\alpha \in E$,

$$[G : F] = [F(\alpha) : F] \leq n.$$ 

However, $\alpha_1, \ldots, \alpha_r \in G$, so these elements form a dependant set. It follows that $[E : F] \leq n$. □

It may turn out that every polynomial over a given field is separable. In this case we say that the field is perfect. As we have seen, fields of characteristic 0 and finite fields are perfect. As an example of a non-perfect field, we may take the field $F_p(t)$, discussed in the previous section. We will now give two criteria for a field to be perfect.

**Proposition 3.3** A field $F$ is perfect if and only if every algebraic extension $E$ of $F$ is separable.

**Proof** Suppose first that the field $F$ is perfect and that $E$ is an algebraic extension of $F$. If $\alpha \in E$, then $m(\alpha, F) \in F[X]$ and so this polynomial is separable. It follows that $E$ is separable.

We now turn to the converse. We suppose that every algebraic extension $E$ of $F$ is separable. Let $f = \lambda g_1 \cdots g_s \in F[X]$, with $\lambda \in F$ and $g_i \in F[X]$ irreducible for all $i$. Let $E$ be a finite (hence algebraic) extension of $F$ containing the roots $\alpha_1, \ldots, \alpha_s$ of $f$. The roots of any $g_i$ are roots of $f$. For a given root $\alpha_k$ of $g_i$, we have $m(\alpha_k, F)|g_i$. As $g_i$ is irreducible, we have $g_i = \lambda m(\alpha_k, F)$, for some $\lambda \in F$. However, the roots of $m(\alpha_k, F)$ are simple, hence those of $g_i$ (the same) are also simple. Therefore $f$ is separable. It follows that $F$ is perfect. □

We now turn to our second criterion.

**Proposition 3.4** Let $F$ be a field of characteristic $p > 0$. Then $F$ is perfect if and only if, for every $a \in F$, there exists $b \in F$ such that $a = b^p$ (or, alternatively $F = F^p$).

**Proof** First let us suppose that for every $a \in F$ we can find $b \in F$ such that $a = b^p$. Let $f \in F[X]$ be irreducible. If $f(X) = a_0 + a_1X + a_2X^2 + \cdots + a_nX^n$, then

$$(b_0 + b_1X + \cdots + X^n)^p = b_0^p + b_1^pX^p + \cdots + b_n^pX^{np} = a_0 + a_1X^p + \cdots + a_nX^{np},$$

hence $f$ is reducible, a contradiction. It follows that at least one nonzero monomial in $f$ has a power which is not a multiple of $p$. This means that the derivative $f'$ is nonzero and so $f$ does not have a multiple root. It now follows that $F$ is perfect.

Now the converse. Suppose that $F$ is perfect and let $a \in F$. We set $f(X) = -a + X^p$ and let $\alpha$ be a root of $f$. Then $a = \alpha^p$ and $f(X) = (\alpha + X)^p$. There is an $r \in \mathbb{N}$ such that $m(\alpha, F) = (\alpha + X)^r$, because $m(\alpha, F)|f(X)$. As $f$ is separable, $r = 1$ and so $\alpha \in F$. Thus we have found a $b \in F$, namely $\alpha$, with $a = b^p$. □

### 3.3 Transitivity of separability

Before looking at the principle theme of this section we will prove a result which is often useful.

**Proposition 3.5** Let $F$, $K$ and $E$ be fields with $K/F$ and $E/K$. If $E$ is separable over $F$, then $K$ is separable over $F$ and $E$ is separable over $K$. 

---

31
PROOF Suppose that the conditions on the fields $F$, $K$ and $E$ are satisfied. First, as $K$ is a subfield of $E$, $K$ is separable over $F$. We now show that $E$ is separable over $K$. If $\alpha \in E$, then $m(\alpha,K)|m(\alpha,F)$. As $m(\alpha,F)$ has no multiple roots, $m(\alpha,K)$ also has no multiple roots, because $m(\alpha,F)$ has no multiple roots. Therefore $E$ is separable over $K$. □

We have seen that we may define a partial order $\mathcal{R}$ on the collection of fields by $F \mathcal{R} E$ if $E$ is an algebraic extension of $F$. In a similar way, we may define a partial order $\mathcal{R}'$ by $F \mathcal{R}' E$ if $E$ is a finite separable extension of $F$. As before the relation $\mathcal{R}'$ is clearly reflexive and antisymmetric, so we only need to prove the transitivity. Here however the proof is more difficult than in the former case. Clearly the difficulty arises only with infinite fields of characteristic $p > 0$. We will begin with some preliminary results.

**Lemma 3.1** Let $f$ be a field of characteristic $p > 0$, $E$ an algebraic extension of $F$ and $\alpha \in E$. We set $m(X) = m(\alpha, F(\alpha^p))$. Then $m$ splits in $E$ and $\alpha$ is the unique root of $m$. If $\alpha$ is separable over $F(\alpha^p)$, then $\alpha \in F(\alpha^p)$.

**Proof** We set $f(X) = -\alpha^p + X^p \in F(\alpha^p)$. Then $f(\alpha) = 0$ and so $m|f$. Now, $f(X) = (-\alpha + X)^p$ and so $m(X) = (-\alpha + X)^r$, for some $r \geq 1$, thus $m$ splits in $E$ and has $\alpha$ as unique root.

If $\alpha$ is separable over $F(\alpha^p)$, then $m$ is irreducible and so $m' \neq 0$. Therefore $m(X) = -\alpha + X$ and $\alpha \in F(\alpha^p)$.

**Lemma 3.2** Let $E$ be a finite extension of $F$, where $F$ is of characteristic $p > 0$. We note $K = F(E^p)$, the subfield of $E$ generated by $F$ and the $p$th powers of elements of $E$. Then $K$ is composed of all the linear combinations of elements of $E^p$ with coefficients in $F$.

**Proof** Let $(\alpha_1, \ldots, \alpha_n)$ be a basis of $E$ over $F$. It is clear that $F(\alpha_1^p, \ldots, \alpha_n^p) \subset K$ and, if $e \in E$, then

$$e = \lambda_1\alpha_1 + \cdots + \lambda_n\alpha_n \implies e^p = \lambda_1^p\alpha_1^p + \cdots + \lambda_n^p\alpha_n^p \implies K \subset F(\alpha_1^p, \ldots, \alpha_n^p).$$

Thus $K = F(\alpha_1^p, \ldots, \alpha_n^p)$.

As $E$ is algebraic over $F$ the elements of $F(\alpha_1^p)$ may be expressed as as polynomials in $\alpha_1^p$ with coefficients in $F$ (see the proof of Proposition 1.4). Now, $\alpha_2^p$ is algebraic over $F$, hence over $F(\alpha_1^p)$. This means that every element of $F(\alpha_1^p, \alpha_2^p)$ may be expressed as a polynomial in $\alpha_2^p$ with coefficients in $F(\alpha_1^p)$. Simplifying such expressions, we see that every element of $F(\alpha_1^p, \alpha_2^p)$ may be expressed as a polynomial in $\alpha_1^p$ and $\alpha_2^p$ with coefficients in $F$. Continuing in the same way we find that every element of $F(\alpha_1^p, \ldots, \alpha_n^p)$ may be expressed as a polynomial in $\alpha_1^p, \ldots, \alpha_n^p$ with coefficients in $F$. This implies that the elements of $F(\alpha_1^p, \ldots, \alpha_n^p)$ are linear combinations of elements of $E^p$, with coefficients in $F$. Of course, linear combinations of elements of $E^p$ belong to $F(\alpha_1^p, \ldots, \alpha_n^p)$ and the result follows. □

We now consider the case where $F(E^p)$ is not a proper subset of $E$, i.e., $E = F(E^p)$.

**Lemma 3.3** We suppose that $E$ be a finite extension of $F$, where $F$ is of characteristic $p > 0$ and that $E = F(E^p)$. If $(\alpha_1, \ldots, \alpha_n)$ is a basis of $E$ over $F$, then so is $(\alpha_1^p, \ldots, \alpha_n^p)$.

**Proof** In the previous lemma we saw that all elements of $F(E^p)$ are linear combinations of $p$th powers of members of $E$. At the beginning of the proof we also saw that a $p$th power of a member of $E$ can be expressed as a linear combination of $p$th powers of a basis, so it follows that $(\alpha_1^p, \ldots, \alpha_n^p)$ is a generating set of $F(E^p) = E$. As $[E:F] = n$, this set must also be a basis of $E$.

The following proposition is interesting in its own right.
Proposition 3.6 Let $E$ be a finite extension of $F$, where $F$ is of characteristic $p > 0$. Then $E$ is a separable extension of $F$ if and only if $E = F(E^p)$.

Proof We suppose first that $E$ is a separable extension of $F$ and take $\alpha \in E$. The minimal polynomial $m(\alpha, F)$ has no multiple roots and so this is the case for the minimal polynomial $m(\alpha, F(\alpha^p))$, because $m(\alpha, F(\alpha^p))|m(\alpha, F)$. Hence $\alpha$ is separable over $F(\alpha^p)$ and, from 3.1, $\alpha \in F(\alpha^p) \subset F(E^p)$. We have $E \subset F(E^p) \subset E$, which implies that $E = F(E^p)$.

We now turn to the converse. Suppose that $E = F(E^p)$. If $E$ is not a separable extension of $F$, then we can find $\alpha \in E$ such that $m(\alpha) = m(\alpha, F)$ is not separable. We have $m(\alpha, F) = m(\alpha, F^p)$:

$$m(X) = b_0 + b_1X^p + \cdots + b_{s-1}X^{(s-1)p} + X^{sp}.$$ 

As $m(\alpha) = 0$, the elements $1, \alpha^p, \ldots, \alpha^{sp}$ are dependant over $F$. However, $m(\alpha)$ is a minimal polynomial, so the elements $1, \alpha^p, \ldots, \alpha^{sp-1}$ are independant over $F$. Also, $sp - 1 \geq 2s - 1 \geq s$, hence $1, \alpha, \ldots, \alpha^s$ are independant over $F$. If necessary we may add vectors to obtain the basis $(1, \alpha, \alpha^p, u_1, \ldots, u_t)$ of $E$ over $F$. From the previous lemma, we know that the $p$th powers of the elements of this basis form a basis and hence that $1, \alpha^p, \ldots, \alpha^{sp}$ form an independant set, a contradiction. Therefore $m$ is separable and so $E$ is a separable extension of $F$. 

We are now in a position to establish the transitivity of finite separable extensions.

Theorem 3.7 Let $F$, $K$ and $E$ be fields, with $K/F$, $E/K$ and $[E:F] < \infty$. If $E$ is separable over $K$ and $K$ separable over $F$, then $E$ is separable over $F$.

Proof From Corollary 3.1 and Proposition 3.1 it is sufficient to consider the case where $F$ is infinite and has a characteristic $p > 0$. From the previous proposition $E = K(E^p)$ and $K = F(K^p)$. Hence

$$E = K(E^p) = F(K^p)(E^p) = F(K^p,E^p) = F(E^p),$$

because $K \subset E$. From the previous proposition again, $E$ is separable over $F$. 

The result which we have just proved enables us to prove another, which seems quite natural.

Theorem 3.8 Let $E$ be an extension of $F$ and $\alpha_1, \ldots, \alpha_n$ elements of $E$ which are algebraic and separable over $F$. If $E = F(\alpha_1, \ldots, \alpha_n)$, then $E$ is separable over $F$.

Proof We only have to consider the case where $F$ is infinite and of characteristic $p > 0$. We note $E_i = F(\alpha_1, \ldots, \alpha_i)$. Thus $E_{i+1} = E_i(\alpha_{i+1})$. We claim that $E_{i+1} = E_i(E_i^p)$. To begin with

$$E_i, E_{i+1} \subset E_{i+1} \implies E_i(E_i^p) \subset E_{i+1}.$$ 

To prove the equality we only need to show that $\alpha_{i+1} \in E_i(E_i^p)$. Now, $\alpha_{i+1}$ is separable over $F$, hence over $E_i(\alpha_i)^p$, because $m(\alpha_{i+1}, E_i(\alpha_i)^p)|m(\alpha_{i+1}, F)$. From Lemma 3.1 $\alpha_{i+1} \in E_i(\alpha_i^p)$ and so $E_i = E_i(E_i^p)$.

Now we can complete the proof. From Proposition 3.6, for each $i$, $E_{i+1}$ is separable over $E_i$. Applying successively Theorem 3.7 we obtain that $E$ is separable over $E_{n-2}$, then that $E$ is separable over $E_{n-3}$ and so on. Finally we obtain that $E$ is separable over $F$. 

Corollary 3.4 If $E$ is the splitting field of a separable polynomial $f \in F[X]$, then $E$ is a separable extension of $F$. 

33
Chapter 4

Properties of finite fields

In the Chapter ?? we introduced finite fields and in Corollary 3.3 we showed that the multiplicative group of such fields is cyclic. We now examine more closely such fields.

Proposition 4.1 If $F_q$ is a finite field, with $q$ elements, then the roots of the polynomial $A(X) = -X + X^q \in F_q[X]$ are the elements of $F_q$.

Proof From Corollary 3.3 we know that $\alpha^{q-1} = 1$, for all $\alpha \in F_q$, which implies that $f(\alpha) = 0$. This is also the case for $\alpha = 0$, so the elements of $F_q$ are all roots of $A$. Since $A$ can have at most $q$ roots, the elements of $F_q$ form a complete set of roots of $A$. \qed

Determining subfields is not difficult.

Theorem 4.1 Let $F_q$ be a finite field, with $q = p^n$ elements, where $p$ is a prime number and $n$ a positive integer. Then a subfield of $F_q$ has $p^m$ elements, for some $m$ dividing $n$. On the other hand, if $m$ divides $n$, then there is a subfield of $F_q$ with $p^m$ elements, and this subfield is unique.

Proof Clearly a subfield $K$ of $F_q$ must have $p^m$ elements, for some $m \leq n$. Let $[F_q : K] = s$ and $B = \{b_1, \ldots, b_s\}$ be a basis of $F_q$ over $K$. The elements $x \in F_q$ can be written $x = k_1 b_1 + \cdots + k_s b_s$, with $k_i \in K$. Since each $k_i$ can take on $p^m$ values, $F_q$ must have exactly $(p^m)^s$ elements. Thus $ms = n$ and so $m$ divides $n$.

Conversely, if $m$ divides $n$, then $p^m - 1$ divides $p^n - 1$, so $f(X) = -1 + X^{p^m-1}$ divides $g(X) = -1 + X^{p^n-1}$ in $F_q[X]$. Hence every root of $B(X) = -X + X^{p^m}$ is a root of $A(X) = -X + X^{p^n}$ and so belongs to $F_q$. Considering $B$ as a polynomial over the field $F_{p^m}$, we see that $F_q$ must contain a splitting field of $B$, which has order $p^m$, because $B$ has $p^m$ distinct roots.

If there were two distinct subfields of order $p^m$ in $F_q$, then the polynomial $B$, which has degree $p^m$, would have more than $p^m$ roots in $F_q$, which is impossible. Therefore, there is a unique subfield of $F_q$ of order $p^m$, where $m$ divides $n$, which consists precisely of the roots of $B$ in $F_q$. \qed

We now consider irreducible polynomials over finite fields. In the first result we use the primitive element theorem.

Proposition 4.2 For any finite field $F_q$ and positive integer $n$, there exists an irreducible polynomial $f \in F_q[X]$ of degree $n$. 

34
PROOF There is a finite extension $E$ of $F_q$ with $q^n$ elements and so $[E : F_q] = n$. From the primitive element theorem, there exists $\alpha \in E$ such that $E = F_q(\alpha)$. The minimal polynomial $m(\alpha, F_q)$ has degree $[F_q(\alpha) : F] = n$, because $E = F(\alpha)$. □

Remark: Since there is only $q$ possibilities for each coefficient, there can only be a finite number of polynomials, a fortiori of irreducible polynomials, of degree $n$ over any $F_q$.

To continue we need two preliminary results.

Lemma 4.1 Let $q = p^n$ and $f \in F_q[X]$ irreducible. If $\alpha$ is a root of $f$ in an extension of $F_q$ and $h \in F_q[X]$, then $h(\alpha) = 0$ if and only if $f$ divides $h$.

PROOF It is sufficient to notice that the minimal polynomial of $\alpha$ is $a^{-1}f$, where $a$ is the leading coefficient of $f$.

Lemma 4.2 Let $f \in F_q[X]$ be irreducible of degree $m$. Then $f$ divides $A(X) = -X + X^{q^m}$ if and only if $m$ divides $n$.

PROOF First suppose that $f$ divides $A$. Let $\alpha$ be a root of $f$ in a splitting of $f$ over $F_q$. Then $-\alpha + \alpha^{q^n} = 0$, so $\alpha \in F_{q^n}$. Thus $F_q(\alpha)$ is a subfield of $F_{q^n}$. Since $[F_q(\alpha) : F_q] = m$, we have

$$n = [F_{q^n} : F_q(\alpha)][F_q(\alpha) : F_q] = [F_{q^n} : F_q(\alpha)]m = m|n.$$ 

Conversely, suppose that $m$ divides $n$. Suppose that $q = p^k$; then $mk$ divides $nk$ and so, by Theorem 4.2, $F_{q^mk}$ contains $F_{q^{mk}}$ as a subfield, i.e., $F_{q^n}$ contains $F_{q^{mk}}$ as a subfield. Let $\alpha$ be a root of $f$ in a splitting field of $f$ over $F_q$. Then $[F_q(\alpha) : F_q] = m$ and so we have

$$m = [F_{q^n} : F_q] = [F_{q^n} : F_q(\alpha)][F_q(\alpha) : F_q] = [F_{q^n} : F_q(\alpha)]m = m.$$ 

It follows that $F_{q^n} = F_q(\alpha)$ and so $\alpha \in F_{q^n} \subset F_{q^n}$. This implies that $\alpha$ is a root of $A(X) = -X + X^{q^n} \in F_q[X]$. Therefore $f$ divides $A$, by Lemma 4.1. □

Corollary 4.1 Let $E$ be an algebraic extension of a finite field $F_q$. Then, for any element $\alpha \in E^*$, there exists a positive integer $n$ such that $\alpha^n = 1$.

PROOF Let $f = \min(\alpha, F_q)$. If the degree of $f$ is $m$, then, using Lemma 4.2 (with $m = n$), we obtain that $f$ divides the polynomial $B(X) = -X + X^{q^n}$. Hence $-\alpha + \alpha^{q^n} = 0$. Multiplying by $\alpha^{-1}$, we obtain $\alpha^{q^n-1} = 1$. □

In the next result we show that the roots of an irreducible polynomial may be expressed as powers of a given root. This will enable us to find an explicit form of a splitting field.

Theorem 4.2 If $f \in F_q[X]$ is of degree $m$, then $f$ has a root $\alpha$ in $F_{q^m}$. Moreover, all the roots of $f$ are simple and are powers of $\alpha$.

PROOF Let $\alpha$ be a root of $f$ in a splitting field of $f$ over $F_q$. A splitting field of $f$ over $F_q$ has the form $F_{q^s}$, with $s \geq 1$, and $F_q(\alpha) \subset F_{q^s}$. If $F_q(\alpha)$ strictly contains $F_{q^m}$, then

$$m = [F_q(\alpha) : F_{q^m}] [F_{q^m} : F_q] = [F_q(\alpha) : F_{q^m}] m > m,$$

a contradiction. Hence $F_q(\alpha) \subset F_{q^m}$, which implies that $\alpha \in F_{q^m}$.

35
If $\beta$ is a root of $f$ in $\mathbb{F}_{q^m}$, then $\beta^q$ is also a root: If $f(X) = \sum_{i=0}^{m} a_i X^i$, with $a_i \in \mathbb{F}_q$, then
\[
\begin{align*}
f(\beta^q) &= a_0 + a_1 \beta^q + \cdots + a_m \beta^{qm} \\
&= a_0^q + a_1^q \beta^q + \cdots + a_m^q \beta^{qm} \\
&= (a_0 + a_1 \beta + \cdots + a_m \beta^m)^q = f(\beta)^q,
\end{align*}
\]
so $\beta^q$ is a root of $f$, as claimed. It follows that the elements $\alpha, \alpha^q, \ldots, \alpha^{q^{m-1}}$ are roots of $f$. These roots are distincts: Suppose, on the contrary, that $\alpha^{q^j} = \alpha^q$, with $0 \leq j < k \leq m - 1$. Then, multiplying by $\alpha^{m-k}$, we obtain
\[
\alpha^{q^{m-k+j}} = \alpha^{q^j} = \alpha.
\]
From Lemma 4.1, $f$ divides the polynomial $A(X) = -X + X^{q^{m-k+j}}$. However, from Lemma 4.2, we have $m$ divides $m - k + j$, which is impossible, because $0 < k - j \leq k - 1$ implies that $0 < m - k + j < m$. Hence the $m$ roots of $f$ in $\mathbb{F}_{q^m}$ are $\alpha, \alpha^q, \ldots, \alpha^{q^{m-1}}$. \hfill $\square$

**Corollary 4.2** If $f$ is an irreducible polynomial in $\mathbb{F}_q[X]$ of degree $m$, then $\mathbb{F}_{q^m}$ is a splitting field of $f$ over $\mathbb{F}_q$.

**Proof** In Theorem 4.2 we established that $\mathbb{F}_{q^m} = \mathbb{F}_q(\alpha)$, where $\alpha$ is a root of $f$ in a splitting field of $f$ over $\mathbb{F}_q$. However, $\mathbb{F}_q(\alpha) = \mathbb{F}_q(\alpha, \alpha^q, \ldots, \alpha^{q^{m-1}})$, which is a splitting field of $f$ over $\mathbb{F}_q$. Therefore $\mathbb{F}_{q^m}$ is a splitting field of $f$ over $\mathbb{F}_q$. \hfill $\square$

Using Lemma 4.2 we may deduce a factorization of the polynomial $A(X) = -X + X^{q^n}$.

**Theorem 4.3** For a finite field $\mathbb{F}_q$ and $n \in \mathbb{N}^*$, the product of all the monic irreducible polynomials over $\mathbb{F}_q$ whose degree divides $n$ is equal to $A(X) = -X + X^{q^n}$.

**Proof** From Lemma 4.2, the monic irreducible polynomials in $\mathbb{F}_q[X]$ which occur in the factorization of $A[X]$ are precisely those whose degree divides $n$. Since $A'(X) = -1 + q^n X^{q^n-1} = -1$, $A$ has no multiple roots in a splitting field over $\mathbb{F}_q$. Thus each monic irreducible polynomial occurring in the factorization of $A$ occurs exactly once. \hfill $\square$

**Example** The monic irreducible polynomials in $\mathbb{F}_2[X]$ are $f_1(X) = X$, $f_2(X) = 1 + X$ and $f_3(X) = 1 + X + X^2$. A simple calculation shows that the product of the $f_i$ is $A(X) = -X + X^4$, which is not surprising, because $4 = 2^2$ and the divisors of 2 are 1 and 2.

**Exercise 4.1** Let $N_q(d)$ be the number of monic irreducible polynomials of degree $d$ in $\mathbb{F}_q[X]$. Show that
\[
q^n = \sum_{d|n} dN_q(d).
\]
Chapter 5

Normal extensions

In this short chapter we will consider another type of extension. Let $E$ be an algebraic extension of $F$ such that any irreducible polynomial $f \in F[X]$ having a root $\alpha \in E$ splits over $E$. In this case we say that $E$ is a normal extension of $F$.

**Proposition 5.1** The algebraic extension $E$ is normal over $F$ if and only if, for each $\alpha \in E$, the minimal polynomial $m(\alpha, F)$ splits over $E$.

**Proof** Let $E$ be a normal extension of $F$ and $\alpha \in E$. The polynomial $m = m(\alpha, F)$ is irreducible and has a root, namely $\alpha$, in $E$. Therefore $m$ splits over $E$.

Now let us suppose that $E$ is an algebraic extension of $F$ and that, for each $\alpha \in E$, the minimal polynomial $m(\alpha, F)$ splits over $E$. Let $f$ be an irreducible polynomial in $F[X]$ and $\beta$ a root of $f$ in $E$. As $m = m(\beta, F)$ and $f$ are irreducible and $m|f$, i.e., $f = cm$, where $c \in F$. As $m$ splits over $E$, so does $f$. Thus $E$ is a normal extension of $F$.

**Example** The number field $\mathbb{Q}(\sqrt[3]{2})$ is not a normal extension of $\mathbb{Q}$. The minimal polynomial $m(\sqrt[3]{2}, \mathbb{Q}) = 2 - X^3$ and the complex roots of this polynomial do not belong to $\mathbb{Q}(\sqrt[3]{2})$.

We have other equivalent conditions particularly when $E$ is a finite extension of $F$. We need a definition. If $F = \{m(\alpha, F) : \alpha \in E\}$ and $A$ the family of roots of the polynomials in $F$, $E$ an extension of $F$ such that $E$ is generated by $F$ and the roots of the $f_i$, then we say that $E$ is a splitting field of $\mathcal{F}$.

**Proposition 5.2** The following conditions are equivalent for an algebraic extension $E$ of $F$:

- **a.** $E$ is a normal extension of $F$;
- **b.** $E$ is the splitting field of a collection of polynomials in $F[X]$;
- **c.** If $C$ is an algebraic closure of $F$, with $E/F$ and $C/E$, and $\sigma : E \rightarrow C$ is an $F$-monomorphism, then $\sigma(E) = E$.

**Proof**

a. $\Rightarrow$ b. Let $\mathcal{F} = \{m(\alpha, F) : \alpha \in E\}$ and $A$ the family of roots of the polynomials in $\mathcal{F}$. If $\alpha \in E$, then $\alpha \in A$ and so $E \subset F(A)$, the subfield of $E$ generated by $F$ and $A$. To see that $F(A) \subset E$ it is sufficient to notice that $F \subset E$, because $E$ is an extension of $F$ and that $A \subset E$, because the extension $E$ is normal. (If $\alpha \in E$, then all the roots of $m(\alpha, F)$ are in $E$).

b. $\Rightarrow$ c. By hypothesis there is a collection of polynomials $\mathcal{F} \subset F[X]$ such that $E = F(A)$, where $A$ is the family of roots of members of $\mathcal{F}$. Let $C$ be an algebraic closure of $F$ containing
and \( \sigma : E \rightarrow C \) a monomorphism. We claim that \( \sigma(A) = A \). Indeed, if \( a \in A \), then \( a \) is a root of a polynomial \( f \in F \); this implies that \( \sigma(a) \) is also a root of \( f \). Thus \( \sigma(A) \subseteq A \) and \( \sigma \) induces an injection from the set of roots of \( f \) into itself. As \( f \) has a finite number of roots, this injection is also a surjection and it follows that \( \sigma(A) = A \). Then

\[
\sigma(E) = \sigma(F(A)) = F(\sigma(A)) = F(A) = E.
\]

\textbf{c.} \( \Rightarrow \) \textbf{a.} Suppose that the condition \textbf{c.} is satisfied and that the extension \( E \) is not normal. Then there exists an irreducible polynomial \( f \in F[X] \) which has roots \( \alpha \) and \( \beta \), with \( \alpha \in E \) and \( \beta \in C \setminus E \). Let \( \sigma \) be the \( F \)-homomorphism of \( F(\alpha) \) into \( C \) such that \( \sigma(\alpha) = \beta \). \( \sigma \) is an \( F \)-monomorphism because \( m(\alpha, F) = m(\beta, F) \). As \( E \) is an algebraic extension of \( F(\alpha) \), from Theorem 2.7, \( \sigma \) may be extended to a monomorphism \( \tau \) of \( E \) into \( C \). However,

\[
\tau(\alpha) = \sigma(\alpha) = \beta \notin E,
\]

and so we have a contradiction to the condition \textbf{c.} It follows that \textbf{c.} \( \Rightarrow \) \textbf{a.} \( \square \)

We have seen that there is a transitivity property for algebraic extensions and for finite separable extensions. However, such a property does not exist for normal extensions. It may be so that \( K \) is a normal extension of \( E \) and \( E \) a normal extension of \( F \), without \( E \) being a normal extension of \( F \). Here is an example. We set \( F = Q \), \( K = F(\alpha) \), where \( \alpha \) is the positive square root of 2 and \( E = F(\beta) \), where \( \beta \) is the positive 4th root of 2. \( K \) is a splitting field of the polynomial \( f(X) = -2 + X^2 \in F[X] \) and so \( K \) is a normal extension of \( F \). Also, \( E \) is a splitting field of the polynomial \( g(X) = -\alpha + X^2 \in K[X] \), so \( E \) is a normal extension of \( K \). Let \( h(X) = -2 + X^2 \in F[X] \). Then \( h \) has a root in \( E \) (in fact, two roots); however, the roots \( \pm i\beta \) are not in \( E \). Therefore, \( E \) is not a normal extension of \( F \).

Although we do not have transitivity, we can say something when we have three fields related by inclusion.

\textbf{Proposition 5.3} Suppose that \( K/F \) and \( E/K \), with \( E \) normal over \( F \). Then \( E \) is normal over \( K \).

\textbf{Proof} As \( E \) is normal over \( F \), by Proposition 5.2 \textbf{a.} \( \Rightarrow \) \textbf{b.}, there is a collection of polynomials \( F \subseteq F[X] \) such that \( E = F(A) \), where \( A \) is the family of roots of the polynomials in \( F \). Now, \( F \subseteq K \) implies that \( F \subseteq K[X] \), hence, by Proposition 5.2 \textbf{b.} \( \Rightarrow \) \textbf{a.}, \( E \) is normal over \( K \). \( \square \)

For finite extensions we have a particularly simple characterization of normality:

\textbf{Theorem 5.1} The finite extension \( E \) of \( F \) is normal if and only if \( E \) is the splitting field of a polynomial \( f \in F[X] \).

\textbf{Proof} Suppose that \( E \) is normal over \( F \). Let \( \alpha_1, \ldots, \alpha_n \) be a basis of \( E \) over \( F \) and \( m_i = m(\alpha_i, F) \), for \( i = 1, \ldots, n \). As \( \alpha_i \in E \) and \( E \) is normal, \( m_i \) splits over \( E \). It follows that \( f = m_1 \cdots m_n \) splits over \( E \). If \( K/F \) and \( E/K \) and \( f \) splits over \( K \), then \( \alpha_1, \ldots, \alpha_n \in K \). As the \( \alpha_i \) form a basis of \( E \), we must have \( K = E \). Therefore \( E \) is a splitting field of \( f \).

For the converse it is sufficient to apply Proposition 5.2 (\textbf{b.} \( \Rightarrow \) \textbf{a.}). \( \square \)

\textbf{Corollary 5.1} A finite extension of a finite field is normal.
proof Let $F$ be a finite field and $E$ a finite extension of $F$, with $[E : F] = n$. As $F$ is finite we know that there is a prime number $p$ and a positive integer $k$ such that $|E| = p^k$. It follows that $[E] = p^{kn}$. Every element $a \in E$ is a root of the polynomial $f(X) = -X + X^{p^k} \in F[X]$. As $\deg f = p^kn$, $f$ splits in $E$. If $K$ is a proper subfield of $E$, then $f$ cannot split in $K$, because at least one element of $E$, i.e., a root of $f$, is missing. Therefore $E$ is a splitting field of $f$ and so, from Theorem 5.1, $E$ is a normal extension of $F$. 

We finish this section with another criterion for an extension to be normal.

**Proposition 5.4** Let $F$ be a field and $\alpha_1, \ldots, \alpha_n$ algebraic over $F$ such that the roots of the minimal polynomials $m(\alpha_i, F)$ lie in $F(\alpha_1, \ldots, \alpha_n)$. Then the field $F(\alpha_1, \ldots, \alpha_n)$ is a normal extension of $F$.

**proof** Let $f$ be the highest common factor of the minimal polynomials $m(\alpha_i, F)$. Then $f \in F[X]$ and $f$ divides the product of the minimal polynomials. Thus every root of $f$ is a root of one of the minimal polynomials and so, by hypothesis, lies in $F(\alpha_1, \ldots, \alpha_n)$. It follows that $F(\alpha_1, \ldots, \alpha_n)$ contains a splitting field of $f$. However, for each $i$, $\alpha_i$ is a root of one of the factors of $m(\alpha_i, F)$ and so is a root of $f$. This means that each $\alpha_i$ must belong to a splitting field of $f$ and so $F(\alpha_1, \ldots, \alpha_n)$ lies in such a field. We have shown that $F(\alpha_1, \ldots, \alpha_n)$ is a splitting field of $f$ and so, by Theorem 5.1, is a normal extension of $F$. 

### 5.1 Normal closures

Let $E$ be an algebraic extension of $F$ and $N$ an algebraic extension of $E$ such that $N$ is normal over $F$. If $N$ is minimal with this property, i.e., there is no proper subfield of $N$ with the same property, then we say that $N$ is a normal closure of $E$ over $F$.

Let $E$ be finite extension of $F$. Then, from Proposition 1.3, $E$ is algebraic over $F$ and there exist $\alpha_1, \ldots, \alpha_n \in E$ such that $E = F(\alpha_1, \ldots, \alpha_n)$. We note $m_i(X) = m(\alpha_i, F)$ and $m(X) = m_1(X) \cdots m_n(X)$ and let $N$ be a splitting field of $m$. $N$ is a finite extension of $F$ containing $E$. As $N$ is a finite extension of $E$, $N$ is algebraic over $E$. From Theorem 5.1, $N$ is a normal extension of $F$. We claim that $N$ is a normal closure of $E$ over $F$. To see this, let $K$ be a subfield of $N$ containing $E$, which is also normal over $F$. From Proposition 5.1, each $m_i$ splits over $K$, hence so does $m$. It follows that $K = N$ and so $N$ is a normal closure of $E$ over $F$. Therefore, at least in the case of finite extensions, normal closures exist. In fact, this is also true for transcendental extensions.

**Lemma 5.1** Let $F$ be a field and $E$ an algebraic extension of $F$. If $\{E_i\}_{i \in I}$ is a collection of subfields of $E$ normal over $F$, then the intersection $K$ of the $E_i$ is normal over $F$.

**proof** The intersection $K$ is clearly a field. If $\alpha \in K$, then $\alpha \in E_i$, for each $i \in I$. This implies that the minimal polynomial $m(\alpha, F)$ splits over $E_i$, for each $i \in I$, and hence over $K$. It follows that $K$ is normal over $F$. 

**Theorem 5.2** If $E$ is an algebraic extension of $F$, then there is a normal closure of $E$ over $F$.

**proof** Let $C$ be an algebraic closure of $E$. Then $C$ is an algebraic extension of $E$, hence of $F$. $C$ is also a normal over $F$. Thus the collection of normal extensions of $F$ containing $E$ is non-empty. Using the lemma, we see that the intersection $N$ of all such extensions of $F$ is normal.
and contains $E$ and so is a normal closure of $E$ over $F$. □

We will now see that normal closures are unique up to isomorphism.

**Theorem 5.3** If $N$ and $N'$ are normal closures of $E$ over $F$, then $N$ and $N'$ are $F$-isomorphic.

**Proof** Let $C$ be an algebraic closure of $F$ and $\sigma : E \rightarrow C$ a $F$-monomorphism. (From Theorem 2.7 such a monomorphism exists.) From Theorem 2.7 again, we can extend $\sigma$ to a monomorphism $\tau$ (resp. $\tau'$) from $N$ (resp. $N'$) into $C$. Then $\tau(N)$ and $\tau'(N')$ are both normal closures of $\sigma(E)$ over $\sigma(F)$. From Lemma 5.1, $\tau(N) \cap \tau'(N')$ is normal over $\sigma(F)$ and contains $\sigma(E)$. By minimality, $\tau(N) = \tau(N) \cap \tau'(N') = \tau'(N')$. If we set $\phi = \tau' \circ \tau$, then $\phi$ is an isomorphism from $N$ onto $N'$. □

**Exercise 5.1** Let $E$ be finite separable extension of $F$ and $N$ a normal closure of $E$ over $F$. Show that $N$ is a finite separable extension of $F$.

An extension $E$ of $F$ is a Galois extension if it is both separable and normal. In the case of fields of characteristic 0 or of finite fields such extensions are very common: the extension $E$ only needs to be a splitting field of a polynomial in $F[X]$. From what we have seen, a finite extension of a finite field is a Galois extension.
Chapter 6

The Galois group

If $E$ is an extension of $F$, then the collection of automorphisms of $E$ fixing $F$, together with the composition of mappings $\sigma$, form a group called the Galois group of the extension $E$ of $F$. We note this group $\text{Gal}(E/F)$. We begin with some basic properties of this group.

**Proposition 6.1** If $E$ is a finite extension of $F$, then the Galois group $\text{Gal}(E/F)$ is finite.

**Proof** Let $(\alpha_i)_{i=1}^n$ be a basis of $E$ over $F$ and let us note $m_i = m(\alpha_i, F)$. If $\sigma \in \text{Gal}(E/F)$, then, for any $\alpha_i$, $\sigma(\alpha_i)$ is a root of $m_i$, hence there is a finite number of choices for $\sigma(\alpha_i)$. As $\sigma$ is determined by the values of the $\sigma(\alpha_i)$ and those of $F$, which are left unchanged by $\sigma$, there is a finite number of automorphisms. \qed

Let us look at some examples of Galois groups.

**Example 1.** $G = \text{Gal}(\mathbb{Q}(\sqrt{2}), \mathbb{Q})$. An element $\sigma \in G$ is determined by its value on $\sqrt{2}$. Since $\sqrt{2}$ is a root of the polynomial $f(X) = -2 + X^2$, so is $\sigma(\sqrt{2})$, which implies that $\sigma(\sqrt{2}) \in \{\pm\sqrt{2}\}$. This leads to two distinct automorphisms, namely the identity and the automorphism $\tau$ defined by $\tau(a + b\sqrt{2}) = a - \sqrt{2}$, hence $G = \{\text{id}_{\mathbb{Q}(\sqrt{2})}, \tau\} \simeq \mathbb{Z}_2$.

**Example 2.** $G = \text{Gal}(\mathbb{Q}(\sqrt[3]{2}), \mathbb{Q})$. An element $\sigma \in G$ is determined by its value on $\sqrt[3]{2}$. Since $\sqrt[3]{2}$ is a root of the polynomial $f(X) = -2 + X^3$, so is $\sigma(\sqrt[3]{2})$. However, $\sigma(\sqrt[3]{2}) \in \mathbb{Q}(\sqrt[3]{2}) \subset \mathbb{R}$, so $\sigma(\sqrt[3]{2}) = \sqrt[3]{2}$, which implies that $\sigma$ is the identity. Thus $G = \{\text{id}_{\mathbb{Q}(\sqrt[3]{2})}\}$.

It is interesting to notice that apparently similar extensions may have quite different Galois groups. It is quite easy to see that the Galois group of $\mathbb{C}$ over $\mathbb{R}$ has just two elements, namely the identity and complex conjugation and so is isomorphic to $\mathbb{Z}_2$. But what can we say of the Galois group of $\mathbb{R}$ over $\mathbb{Q}$?

**Example 3.** $G = \text{Gal}(\mathbb{R}/\mathbb{Q})$. Let $\sigma \in G$ and suppose that $a < b$. Then $b - a = y^2$, for some $y \neq 0$, and

$$\sigma(b) - \sigma(a) = \sigma(b - a) = \sigma(y^2) = \sigma(y)^2 > 0 \implies \sigma(a) < \sigma(b).$$

If $\sigma \neq \text{id}_\mathbb{R}$, then there exists $x$ such that $\sigma(x) \neq x$. If $\sigma(x) > x$, then there exists a rational number $r$ such that $x < r < \sigma(x)$, and $\sigma(x) < \sigma(r) < \sigma^2(x)$. However, $\sigma(r) = r$, because $r \in \mathbb{Q}$, so we have a contradiction, hence $\sigma(x) \neq x$. A similar argument shows that $\sigma(x) \neq x$ and it follows that $\sigma$ is the identity on $\mathbb{R}$. Therefore $G = \{\text{id}_\mathbb{R}\}$. 

41
If the extension $E$ of $F$ is Galois, then we can be more precise.

**Theorem 6.1** If $E$ is a finite Galois extension of $F$, then we have $|\text{Gal}(E/F)| = [E : F]$.

**Proof** As $E$ is a finite normal extension of $F$, $E$ is the splitting field of a polynomial $f \in F[X]$, which is a product of minimal polynomials (see Theorem 5.1 and its proof). However, the extension $E$ is also separable, hence the minimal polynomials in the product are separable and it follows that $E$ is a splitting field of a separable polynomial. Now applying Theorem 3.1 with $E' = E$, $F' = F$ and $\sigma$ the identity, we obtain the result. \qed

**Remark** From Theorem 6.1, the extension $\mathbb{Q}(\sqrt{2})$ is not Galois.

### 6.1 Fundamental theorem of Galois theory

In this section we consider the relation between extensions of a field $F$ included in a given extension $E$ and subgroups of the Galois group $\text{Gal}(E/F)$. We begin with two definitions. For $H$, a subgroup of $\text{Gal}(E/F)$, we write

$$\mathcal{F}(H) = \{x \in E : \sigma(x) = x, \forall \sigma \in H\}.$$  

We often write $E^H$ for $\mathcal{F}(H)$. It is easy to check that $F \subseteq \mathcal{F}(H) \subseteq E$. $E^H$ is called the fixed field of $H$ in $E$. For an intermediate field $K$, i.e., $K/F$ and $E/K$, we set

$$\mathcal{G}(K) = \text{Gal}(E/K) = \{\sigma \in \text{Gal}(E/F) : \sigma(x) = x, \forall x \in K\}.$$  

It is not difficult to show that $\mathcal{G}(K)$ is a subgroup of $\text{Gal}(E/F)$.

We will note $\mathcal{S}(\text{Gal}(E/F))$, or just $\mathcal{S}(G)$, the set of subgroups of $\text{Gal}(E/F)$ and $\mathcal{T}(E/F)$, or just $\mathcal{T}$, the set of intermediate fields between $F$ and $E$. With inclusion both of these sets are partially ordered.

We recall that, if $(A, \leq_a)$ and $(B, \leq_b)$ are partially ordered sets and $\phi$ is a mapping from $A$ into $B$ such that, for $x, y \in A$,  

$$x \leq_a y \implies \phi(x) \leq_b \phi(y),$$  

then $\phi$ is said to order-preserving. On the other-hand, if  

$$x \leq_a y \implies \phi(y) \leq_b \phi(x),$$  

then $\phi$ is said to order-reversing. It is not difficult to see that the mappings $\mathcal{F}$ and $\mathcal{G}$ are order-reversing.

**Theorem 6.2** Suppose that $E$ is a finite extension of $F$. Then $E$ is Galois extension if and only if $\mathcal{F}(G) = F$, where $G = \text{Gal}(E/F)$.

**Proof** Let us first suppose that $E$ is a Galois extension of $F$. We set $F_0 = \mathcal{F}(G)$. As $F \subseteq F_0$, every $F_0$-automorphism is an $F$-automorphism. If there is an $F$-automorphism $\sigma$ which is not an $F_0$-automorphism, then we can find an element $y \in F_0 \setminus F$ such that $\sigma(y) \neq y$. However, by definition of $F_0$, this is not possible, and so every $F$-automorphism is an $F_0$-automorphism. As $E$ is separable over $F$ and $F_0$ is an intermediate field, $E$ is separable over $F_0$ (Proposition 3.5). Therefore, using Theorem 6.1, we have

$$[E : F] = |\text{Gal}(E/F)| = |\text{Gal}(E/F_0)| = [E : F_0]$$  

42
and it now follows that $F_0 = F$.

We now turn to the converse. We suppose that $F(G) = F$. From Proposition 6.1 we know that the Galois group $G = Gal(E/F)$ is finite. Let $G = \{\sigma_1, \ldots, \sigma_n\}$, with $\sigma_1$ the identité. We need to show that the extension $E$ is both normal and separable. We will first show that it is normal. We consider an irreducible polynomial $f \in F[X]$ with a root $\alpha$ in $E$. Applying the automorphisms $\sigma_i$ to $\alpha$, we obtain $r$ distinct images:

$$\alpha = \alpha_1 = \sigma_1(\alpha), \alpha_2 = \sigma_2(\alpha), \ldots, \alpha_r = \sigma_r(\alpha),$$

where we have supposed that the first $r$ automorphisms give the distinct images. Let us write

$$e_1 = \sum_{i=1}^r \alpha_1, \quad e_2 = \sum_{i<j} \alpha_i\alpha_j, \quad e_3 = \sum_{i<j<k} \alpha_i\alpha_j\alpha_k, \ldots, \quad e_r = \prod_{i=1}^r \alpha_i.$$

(These expressions are just the evaluations at $(\alpha_1, \ldots, \alpha_r)$ of the elementary polynomials in $E(X_1, \ldots, X_r)$.)

Any $\sigma \in G$ permutes the $\alpha_i$ and so, for each $i$, we have $\sigma(e_i) = e_i$. Therefore the $e_i$ belong to $F(G) = F$. We now consider the polynomial

$$g(X) = (-\alpha_1 + X) \cdots (-\alpha_r + X) = (-1)^r e_r + \cdots + e_2 X^{r-2} - c_1 X^{r-1} + X^r \in F[X].$$

We claim that $g = m(\alpha, F)$. Let $h(X) = \sum_{i=0}^m b_i X^i$, with $h(\alpha) = 0$. Then, for every $i$,

$$0 = \sigma_i(h(\alpha)) = h(\sigma_i(\alpha)) = h(\alpha_i).$$

As the roots of $g$ are roots of $h$, $g$ divides $h$ and so $g = m(\alpha, F)$ as claimed.

We now return to the polynomial $f$. As $f$ is irreducible and has $\alpha$ as a root, there is a constant $c \in F$ such that $f = cg$. As the $\alpha_i \in E$, $g$ splits over $E$, and so does $f$. We have shown that $E$ is a normal extension.

We now show that the extension $E$ is also separable. We take $\alpha \in E$. The polynomial $g$ which we defined above is the minimal polynomial $m(\alpha, F)$ and this has distinct roots. Hence $\alpha$ is a separable element and it follows that the extension $E$ is separable over $F$.

In the last result we saw that, in the case of a finite Galois extension, $F(G) = F$. It is natural to ask whether there is a subgroup $H$ of $G$ such that $F(H) = F$. In the next theorem, we will see that the answer is negative.

**Theorem 6.3** If $E$ is a finite Galois extension of $F$ and $H$ a proper subgroup of the Galois group $G = Gal(E/F)$, then $F$ is properly contained in $F(H)$.

**Proof** We will give a proof by contradiction. Suppose that $H$ is a proper subgroup of $G$ and that $F(H) = F$. As $E$ is a finite separable extension of $F$ we may apply the primitive element theorem (Theorem 3.3): there exists $\alpha \in E$ such that $E = F(\alpha)$. We define a polynomial $f \in E[X]$ by

$$f(X) = \prod_{\sigma \in H} (-\sigma(\alpha) + X).$$

For $\tau \in H$, we define the polynomial $\tau f$ by applying $\tau$ to the coefficients of $f$. It is easy to see that

$$\tau f(X) = \prod_{\sigma \in H} (-\tau \sigma(\alpha) + X) = f(X).$$

43
Therefore the coefficients of $F$ are fixed by $\tau$, which implies that $f \in F[X]$, because $F(H) = F$.

Now we notice that $\alpha$ is a root of $f$. (It is sufficient to take $\sigma = \text{id}$). Thus

$$\deg f = |H| < |G| = [E : F] = [F(\alpha) : F] = \deg m(\alpha, F) \leq \deg f,$$

a contradiction. This establishes the result. 

We now turn to the fundamental theorem of Galois theory. The theorem has three parts, which we will handle separately.

**Theorem 6.4** Let $E$ be a finite Galois extension of a field $F$, with Galois group $G$. As above we write $\mathcal{S}$ the set of subgroups of $G$ and $\mathcal{T}$ for the set of intermediate fields between $F$ and $E$. Then the mappings $\mathcal{F} : \mathcal{S} \rightarrow \mathcal{T}$ and $\mathcal{G} : \mathcal{T} \rightarrow \mathcal{S}$ are bijections, each one being the inverse of the other.

**Proof** First, let us consider the mapping $\mathcal{F}G$. We take a subgroup $H$ of $G$. Then $\sigma \in H = \Rightarrow \sigma \in \text{Gal}(E/F(H)) = \mathcal{GF}(H)$.

Therefore $H \subset \mathcal{GF}(H)$. Suppose that we do not have equality. Using Propositions 3.5 and 5.3 we see that $E$ is a finite Galois extension of $F(H)$. As $H$ is a proper subgroup of $\mathcal{GF}(H) = \text{Gal}(E/F(H))$, from Theorem 6.3, with $F(H)$ as $F$, then $F(H)$ is properly contained in itself, a contradiction. It follows that we have $H = \mathcal{GF}(H)$.

We now consider the mapping $\mathcal{FG}$. Let $K$ be a field intermediate between $F$ and $E$. Using Propositions 3.5 and 5.3 we see that $E$ is a finite Galois extension of $K$. Then, from Theorem 6.2, $\mathcal{F}(\text{Gal}(E/K)) = K$, i.e., $\mathcal{FG}(K) = K$. This finishes the proof. 

Up to now we have seen that, in the case of finite Galois extensions, the mappings $\mathcal{F}$ and $\mathcal{G}$ are order-reversing bijections. We will now see that these mappings have other properties, namely they associate certain types of subgroups with particular sorts of intermediate fields.

We need a definition. If $K$ is a subfield of a field $E$ and $\sigma$ an automorphism of $E$, then $\sigma(K)$ is a subfield of $E$. Such a subfield is called a conjugate subfield of $K$.

**Theorem 6.5** Let $E$ be a finite Galois extension of $F$ and $G$ the associated Galois group. If $H$ is a subgroup of $G$, $\sigma \in G$ and $K = F(H)$, then $\mathcal{F}(\sigma H \sigma^{-1}) = \sigma(K)$, i.e., $\mathcal{F}$ associates a conjugate subgroup to a corresponding conjugate subfield.

**Proof** We have

$$\mathcal{F}(\sigma H \sigma^{-1}) = \{ x \in E : \sigma \tau \sigma^{-1}(x) = x \ \forall \tau \in H \} = \{ x \in E : \tau(\sigma^{-1}(x)) = \sigma^{-1}(x) \ \forall \tau \in H \} = \{ x \in E : \sigma^{-1}(x) \in \mathcal{F}(H) \} = \sigma(K).$$

This ends the proof. 

We now consider normal subgroups of the Galois group. We notice first that, if $K$ is an intermediate field, then $E$ is always a normal extension of $K$ (Proposition 5.3); however, $K$ may not be a normal extension of $F$. 

44
Theorem 6.6 Suppose that $E$ is a finite Galois extension of $F$ and $G$ the associated Galois group. Then $K$ is a normal extension of $F$ if and only if $H = \text{Gal}(E/K)$ is a normal subgroup of $G$. In this case the Galois group $\text{Gal}(K/F)$ is isomorphic to the quotient group $G/H$.

In addition, for any subgroup $H$ (not necessarily normal),

$$[K:F] = [G:H] \quad \text{and} \quad [E:K] = [H].$$

Proof Let $K$ be an intermediate field which is a normal extension of $F$ and $C$ an algebraic closure of $F$, with $C/F$. (From Exercise 2.3 such an algebraic closure exists.) Suppose that $\sigma$ is an $F$-monomorphism from $K$ into $E$, thus into $C$. As $K$ is separable over $E$, we may extend $\sigma$ to an $F$-monomorphism $\hat{\sigma} : E \to C$ (Theorem 3.2). As $E$ is a normal extension of $F$, from Proposition 5.2, $\hat{\sigma}$ is an $F$-automorphism of $E$. Hence, every $F$-monomorphism $\sigma$ of $K$ into $E$ is a restriction of an $F$-automorphism $\hat{\sigma}$ of $E$. In addition, clearly every $F$-automorphism of $E$ restricted to $K$ is an $F$-monomorphism of $K$ into $E$. Thus the $F$-monomorphisms from $K$ into $E$ are the restrictions to $K$ of $\hat{\sigma}$-automorphisms of $E$, i.e., of elements of $\tau \in G$. As $K$ is a normal extension of $F$, using Proposition 5.2 again, we see that $\tau$ is an $F$-automorphism of $K$. If $K = \mathcal{F}(H)$, then with Theorem 6.5 we have

$$\mathcal{F}(H) = K = \tau(K) = \mathcal{F}(\tau H \tau^{-1}) \implies H = \tau H \tau^{-1},$$

and so $H$ is a normal subgroup of $G$.

Now we suppose that $H$ is a normal subgroup of $G$. For any $\sigma \in G$, we have $H = \sigma H \sigma^{-1}$. Then, for $K = \mathcal{F}(H)$,

$$\sigma(K) = \mathcal{F}(\sigma H \sigma^{-1}) = \mathcal{F}(H) = K.$$

Let $f \in F[X]$ be irreducible with a root $\alpha \in K$. Because $K \subseteq E$ and $E$ is a normal extension of $F$, all the roots of $f$ lie in $E$, so $E$ contains a splitting field $S$ of $f$, which is an extension of $K$. If $\alpha'$ is another root of $f$, then using Proposition 2.2 with $\sigma = \text{id}$, we may find an $F$-isomorphism $\sigma : F(\alpha) \to F(\alpha')$, which is such that $\sigma(\alpha) = \alpha'$. Now, applying Theorem 2.2, we can extend $\sigma$ to an $F$-automorphism $\sigma'$ of $E'$. We would like to extend $\sigma'$ to an $F$-automorphism of $E$. We take an algebraic closure $C$ of $E'$, which is an extension of $E$. Then we may consider $\sigma'$ as a monomorphism of $E'$ into $C$, which we can extend to $\hat{\sigma} : E \to C$. However, $E$ is a normal extension of $E'$, because $E$ is such an extension of $F$ and so, from Proposition 5.2, $\hat{\sigma}(E) = E$. Thus, $\hat{\sigma}$ is an $F$-automorphism of $E$, such that $\hat{\sigma}(\alpha) = \alpha'$. As $\hat{\sigma}(K) = K$ and $\alpha \in K$, $\alpha' \in K$. It follows that $K$ is a normal extension of $F$.

We have proved the hardest part of the theorem. Now we turn to the remaining parts. First, we show that $\text{Gal}(K/F) \simeq G/H$, if $H \triangleleft G$. Consider the mapping

$$\phi : \text{Gal}(E/F) \to \text{Gal}(K/F), \sigma \mapsto \sigma|_K.$$

In the first part of the proof we saw that the elements of the Galois group $\text{Gal}(K/F)$ are the restrictions to $K$ of the elements of the Galois group $\text{Gal}(E/F)$. Hence, the mapping $\phi$ is an epimorphism. Also,

$$\text{Ker } \phi = \{ \sigma \in \text{Gal}(E/F) : \sigma|_K = \text{id}|_K \} = \text{Gal}(E/K) = H.$$

It follows that

$$\text{Gal}(E/F)/H \simeq \text{Gal}(K/F).$$

To conclude, we notice that

45
and

\[ [E : K] = \frac{[E : F]}{[K : F]} = \frac{|G|}{|G/H|} = |H|. \]

This ends the proof.

**Remark** We may sum up the results of Theorem 6.6 in the following way. If \( H \) is a subgroup of the Galois group \( G = \text{Gal}(E/F) \) and \( K \) the corresponding intermediate field between \( F \) and \( E \) (\( K = \mathcal{F}(H) \)), then

\[ [E : K] = |H| = |\text{Gal}(E/K)| \]

and

\[ [K : F] = [G : H]. \]

If, in addition, \( H \) is a normal subgroup of \( G \), then \( K \) is a normal extension of \( F \) and we may extend the second line to obtain

\[ [K : F] = [G : H] = |G/H| = |\text{Gal}(K/F)|. \]

The Theorems 6.4, 6.5 and 6.6 which we have just proved are usually handled together under the name of the fundamental theorem of Galois theory. As two of the parts are rather long, it seems to us preferable to divide the theorem into parts.

We have seen that a finite extension \( E \) of a field \( F \) gives rise to a finite group of automorphisms of \( E \), namely the Galois group \( \text{Gal}(E/F) \). Suppose now that we have a finite group of automorphisms \( G \) of a field \( E \). It is natural to ask whether there exists a subfield \( F \) of \( E \) such that \( G \) is the Galois group \( \text{Gal}(E/F) \). This is in fact the case as we will now see.

Let \( E \) be a field and \( G \) a finite subgroup of the group of automorphisms of \( E \). We suppose that \( |G| = n \) and set

\[ F = E^G = \{ x \in E : g(x) = x, \forall g \in G \}. \]

\( F \) is clearly a subfield of \( E \); it is called the fixed field of \( G \) in \( E \).

**Theorem 6.7 (Artin)** The field \( E \) is a finite Galois extension of \( F \) and

\[ \text{Gal}(E/F) = G. \]

**Proof** We define an action \( \Phi \) of the group \( G \) on \( E \):

\[ \Phi : G \times E \rightarrow E, (g, x) \rightarrow g(x). \]

Let us take \( \alpha \in E \) and note \( O_\alpha \) the orbit of \( \alpha \):

\[ O_\alpha = \{ g(\alpha) : g \in G \} = \{ \alpha_1, \ldots, \alpha_s \}, \]

with \( \alpha_1 = \alpha \) and \( s \leq n \). We set

\[ f(X) = \prod_{k=1}^{s} (-\alpha_k + X). \]

An element of \( G \) permutes the \( \alpha_i \); given that the coefficients of the polynomial \( f \) are symmetric polynomials in the \( \alpha_i \), these coefficients are fixed by \( G \) and so \( f \in F[X] \). Hence every element \( \alpha \in E \) is the root of a \( f \in F[X] \), with \( \deg f \leq n \). As the roots of \( f \) are distinct, \( E \) is a separable extension of \( F \). From Proposition 3.2, \( E \) is a finite extension of \( F \) and \( [E : F] \leq n \).
We need to show that $E$ is a normal extension of $F$. From the primitive element theorem, there exists $α ∈ E$ such that $E = F(α)$. As the roots of the minimal polynomial $m(α, F)$ lie in the orbit of $α$, which is contained in $E$, $E$ is a splitting field of $m(α, F)$; it follows from Theorem 5.1 that $E$ is a normal extension of $F$. We have shown that $E$ is a Galois extension of $F$.

To conclude, we show that $G$ is the Galois group $Gal(E/F)$. By definition of $F$, every element of $G$ fixes the elements of $F$, so $G ⊂ Gal(E/F)$. In addition, from Theorem 6.1, we know that $|Gal(E/F)| = [E : F] ≤ n$, hence

$$n = |G| ≤ |Gal(E/F)| ≤ n$$

and it follows that

$$G = Gal(E/F).$$

This ends the proof. $\square$

The theorem which we have just proved has an interesting application. We recall a definition. If $F$ is a field and $F[X_1, \ldots, X_n]$ is the ring of polynomials in $n$ variables with coefficients in $F$, then we write $F(X_1, \ldots, X_n)$ for the field of fractions of $F[X_1, \ldots, X_n]$. This field is called the field of rational functions in $n$ variables over $F$. The rational fractions of the symmetric polynomials form a subfield of $F(X_1, \ldots, X_n)$, which we will note $F_S(X_1, \ldots, X_n)$. We are interested in finding the degree of the extension $F(X_1, \ldots, X_n)/F_S(X_1, \ldots, X_n)$ and its Galois group.

If $σ ∈ S_n$, then the mapping defined by $X_i \mapsto X_{σ(i)}$ induces an automorphism $σ$ of the field $F(X_1, \ldots, X_n)$. The mapping $σ \mapsto σ$ is a group monomorphism, so $S_n$ may be considered to be a subgroup of the group of automorphisms of $F(X_1, \ldots, X_n)$. The fixed field of $S_n$ is clearly $F_S(X_1, \ldots, X_n)$. From Artin’s theorem (Theorem 6.7) we deduce that $F(X_1, \ldots, X_n)$ is a finite Galois extension of $F_S(X_1, \ldots, X_n)$, with Galois group $S_n$. It follows that the dimension of $F(X_1, \ldots, X_n)$ over $F_S(X_1, \ldots, X_n)$ is $n!$.

**Conjugates in Galois extensions**

If $E$ is a finite field extension of a field $F$ and $α ∈ E$, then we say that any root of the minimal polynomial $m(α, F)$ is an $(F)$-conjugate of $α$. It is clear that, for all $σ ∈ Gal(E/F)$, $σ(α)$ is an $F$-conjugate of $α$. However, in general, not all conjugates of $α$ are of this form. For example, the $\mathbb{Q}$-conjugates of $\sqrt{2}$ are $\sqrt{2}$, $j\sqrt{2}$ and $j^2\sqrt{2}$, where $j$ is a primitive 3rd root of unity. If $σ ∈ Gal(\mathbb{Q}(\sqrt{2}), \mathbb{Q})$, then $\text{Im}(σ) ⊂ \mathbb{R}$, so there is no $σ ∈ Gal(\mathbb{Q}(\sqrt{2}), \mathbb{Q})$ such that $σ(\sqrt{2}) = j\sqrt{2}$. The following result ensures that, if $E/F$ is a finite normal extension, then all $F$-conjugates of an element $α ∈ E$ are images of $α$ by an element in the Galois group.

**Proposition 6.2** If $E$ is a finite normal extension of $F$ and $α ∈ E$ then the set

$$A = \{σ(α) : σ ∈ Gal(E/F)\}$$

is the set of conjugates of $α$.

**Proof** If $β$ is a conjugate of $α$, then, from Proposition 2.3, there is an $F$-isomorphism $φ : F(α) \rightarrow F(β)$ such that $φ(α) = β$, since $m(α, F) ∈ F[X]$ is irreducible. Both $F(α)$ and $F(β)$ are subfields of $E$. (As $E$ is a normal extension of $F$, we may suppose that all the conjugates of $α$ lie in $E$.) From Theorem 5.1 there exists a polynomial $g ∈ F[X]$ whose splitting field is $E$. Now, $g ∈ F(α)[X]$ and, in the notation of Theorem 2.2, with $φ = σ$, we have $g^σ = g$. It follows that there exists $σ' ∈ Gal(E/F)$ such that $σ'(α) = β$. $\square$
We have shown, at least in the case where $E$ is a normal extension of $F$, that the set of conjugates of the element $\alpha \in F$ is composed of elements of the form $\sigma(\alpha)$, where $\sigma \in \text{Gal}(E/F)$. However, it may be so that there are members $\sigma, \tau \in \text{Gal}(E/F)$ such that $\sigma(\alpha) = \tau(\alpha)$. We are interested in knowing the number of automorphisms $\sigma \in \text{Gal}(E/F)$ which give us the same conjugate.

**Proposition 6.3** Let $E$ be a finite Galois extension of $F$, $\alpha \in E$ and $\beta$ a conjugate of $\alpha \in L$. Then the number of $\sigma \in \text{Gal}(E/F)$ such that $\sigma(\alpha) = \beta$ is equal to the dimension $[E : F(\alpha)]$.

**Proof** Let $\beta$ be a conjugate of $\alpha$. There exists $\sigma' \in \text{Gal}(E/F)$ such that $\sigma'(\alpha) = \beta$. We have
\[
\{ \sigma \in \text{Gal}(E/F) : \sigma(\alpha) = \beta \} = \{ \sigma \in \text{Gal}(E/F) : \sigma(\alpha) = \sigma'(\alpha) \} = \{ \sigma \in \text{Gal}(E/F) : \sigma'^{-1}\sigma(\alpha) = \alpha \}.
\]
Thus we have a bijection between the automorphisms $\sigma \in \text{Gal}(E/F)$ such that $\sigma(\alpha) = \beta$ and the automorphisms $\sigma \in \text{Gal}(E/F)$ such that $\sigma(\alpha) = \alpha$. However, $\sigma \in \text{Gal}(E/F)$ fixes $\alpha$ if and only if $\sigma \in \text{Gal}(E/F(\alpha))$. From Theorem 6.6 we have
\[
|\text{Gal}(E/F(\alpha))| = [E : E^{\text{Gal}(E/F(\alpha))}],
\]
where $E^{\text{Gal}(E/F(\alpha))}$ is the fixed field of $\text{Gal}(E/F(\alpha))$. Moreover, by Propositions 3.5 and 5.3 $E$ is a Galois extension of $F(\alpha)$. Using Theorem 6.2 we obtain
\[
E^{\text{Gal}(E/F(\alpha))} = F(\alpha)
\]
and so
\[
[E : E^{\text{Gal}(E/F(\alpha))}] = [E : F(\alpha)].
\]
This ends the proof. \qed

**Remark** If $E$ is a Galois extension of $F$ and the conjugates of an element $\alpha \in E$ are distinct, then it is natural to ask whether these elements form a basis of $E$ over $F$. (If $E$ is a Galois extension of $F$, then $|\text{Gal}(E/F)| = [E : F]$.) This is not in general the case. However, the normal basis theorem ensures that for some $\alpha \in E$ this is the case. (For a proof, see for example [23]).

### 6.2 Composita

In this section we will be primarily interested in intersections of subgroups of the Galois group. We begin with a definition. If $K$ and $L$ are subfields of a field $E$, then the intersection of all subfields of $E$ containing these fields, which we note $KL$, is called the *compositum* of $K$ and $L$. Clearly $KL$ is the smallest subfield of $E$ containing $K$ and $L$. Of course we may easily generalize this definition to more than two subfields, even to an infinite number of subfields.

The subset $R$ of $E$ defined by
\[
R = \left\{ \sum_{i \in I} k_i l_i : k_i \in K, l_i \in L, |I| < \infty \right\}
\]
is the smallest subring of $E$ containing both $K$ and $L$. The ring of fractions of $R$ is the compositum $KL$ in $E$. 48
Theorem 6.8 Let $K$ and $L$ be extensions of $F$ in $E$, where $K$ is a finite Galois extension of $F$. Then

- **a.** $KL$ is a finite Galois extension of $L$;
- **b.** If $\sigma \in \text{Gal}(KL/L)$, then the restriction of $\sigma$ to $K$ belongs to $\text{Gal}(K/F)$ and the mapping $\phi: \text{Gal}(KL/L) \longrightarrow \text{Gal}(K/F), \sigma \longmapsto \sigma|_K$ is a monomorphism;
- **c.** $K$ is a Galois extension of $K \cap L$ and the image of $\phi$ is $\text{Gal}(K/K \cap L)$; $\phi$ is an isomorphism if and only if $K \cap L = F$.

**Proof.**

**a.** From the primitive element theorem there is an element $\alpha \in K$ such that $K = F(\alpha)$, hence $KL = LF(\alpha) = L(\alpha)$. As $\alpha$ is algebraic over $F$, therefore over $L$, $L(\alpha)$ is a finite extension of $L$. As $K$ is a separable extension of $F$, $\alpha$ is separable over $F$, hence over $L$, and it follows that $L(\alpha)$ is separable over $L$. We have shown that $KL$ is separable over $L$.

We now need to show that $KL$ is a normal extension of $L$. Let $f = m(\alpha, F)$ and $g = m(\alpha, L)$. Then $g|f$. As $f$ has a root $\alpha \in K$ and $K$ is a normal extension of $F$, all the roots of $f$ are in $K$. It follows that all the roots of $g$ are in $K \subset KL = L(\alpha)$ and so $L(\alpha)$ is a splitting field of $g$. Thus $KL$ is a normal extension of $L$.

**b.** Let $\sigma \in \text{Gal}(KL/L)$. We need to show that $\sigma(K) = K$ and $\sigma|_K$ fixes $F$. For any $\alpha \in K$, $\sigma(\alpha)$ is a root of the minimal polynomial $m(\alpha, F)$. As $K$ is a normal extension of $F$, $\sigma(\alpha) \in K$. Thus $\sigma(K) \subset K$. In the same way, $\sigma^{-1}(K) \subset K$ and so $\sigma(K) = K$. In addition, the fact that $F \subset L$ implies that $\sigma$ fixes $F$ and so $\sigma|_K$ fixes $F$. Therefore $\sigma|_K \in \text{Gal}(K/F)$. If $\tau \in \text{Gal}(KL/L)$ and $\alpha \in K$, then $(\sigma \circ \tau)|_K(\alpha) = (\sigma \circ \tau)(\alpha) = \sigma(\tau(\alpha)) = \sigma|_K \circ \tau|_K(\alpha)$,

therefore $\phi$ is a homomorphism.

We now need to show that $\phi$ is injective. If $\sigma|_K$ fixes each element of $K$, then $\sigma$ fixes each element of $K$ and each element of $L$ and so fixes each element of $KL$. This establishes the injectivity of $\phi$. Hence $\phi$ is a monomorphism.

**c.** First we show that $K$ is a Galois extension of $K \cap L$. As $F \subset K \cap L \subset K$ and $K$ is a Galois extension of $F$, from Propositions 3.5 and 5.3, $K$ is a Galois extension of $K \cap L$.

We set $A = \text{Im} \phi$. $A$ is a subgroup of the Galois group $\text{Gal}(K/F)$, thus, by Theorem 6.4, $A = \text{Gal}(K/K^A)$. Moreover,

$$K^A = \{x \in K : \sigma(x) = x \forall \sigma \in \text{Gal}(KL/L)\},$$

since the elements of $A$ are restrictions of elements of $\text{Gal}(KL/L)$ to $K$. Theorem 6.2 ensures that any element of $KL$ fixed by all elements of $\text{Gal}(KL/L)$ lies in $L$. Hence

$$K^A = K \cap L$$

and $A = \text{Gal}(K/K \cap L)$, i.e. $\text{Im} \phi = \text{Gal}(K/K \cap L)$, as claimed.

Now, $\phi$ is an isomorphism if and only if $\text{Gal}(K/K \cap L) = \text{Gal}(K/F)$. However, Theorem 6.2 ensures that $K^{\text{Gal}(K/K \cap L)} = K \cap L$ and $K^{\text{Gal}(K/F)} = F$. Finally, $\phi$ is an isomorphism if and only if $K \cap L = F$. This finishes the proof.

The theorem we have just proved has an interesting corollary linking the degrees of the extensions over $F$.
Corollary 6.1 Under the conditions of Theorem 6.8, we have

\[ [KL : F] = \frac{[K : F][L : F]}{[K \cap L : F]} \]

Proof We have

\[ [KL : F] = [KL : L][L : F] \implies \frac{[KL : F]}{[L : F]} = [KL : L] \]

and

\[ [K : F] = [K : K \cap L][K \cap L : F] \implies \frac{[K : F]}{[K \cap L : F]} = [K : K \cap L]. \]

From the previous theorem, \( KL \) is a Galois extension of \( L \) and there is no difficulty in seeing that this is also the case for \( K \) over \( K \cap L \). Hence,

\[ [KL : L] = |Gal(KL/L)| = |Gal(K/K \cap L)| = [K : K \cap L]. \]

The second equality holds, because in the proof of Theorem 6.8 we showed that the Galois groups \( Gal(KL/L) \) and \( Gal(K/K \cap L) \) are isomorphic. The result now follows. \( \square \)

Exercise 6.1 Show that \([KL : L]\) divides \([K : F]\).

We may now consider the image under \( \mathcal{F} \) of the intersection of two subgroups of the Galois group and of the group generated by two subgroups.

Theorem 6.9 Let \( E \) be a finite Galois extension of \( F \) and \( H_1, H_2 \) subgroups of the Galois group \( G = Gal(E/F) \). We note \( K_1 = \mathcal{F}(H_1) \) and \( K_2 = \mathcal{F}(H_2) \). Then \( \mathcal{F}(H_1 \cap H_2) = K_1K_2 \) and, if \( H \) is the subgroup generated by \( H_1 \cup H_2 \), then \( \mathcal{F}(H) = K_1 \cap K_2 \).

Proof If \( \sigma \) fixes each element of \( K_1K_2 \), then \( \sigma \) fixes each element of \( K_1 \) and each element of \( K_2 \), hence \( \sigma \in H_1 \cap H_2 \). On the other hand, suppose that \( \sigma \in H_1 \cap H_2 \). Then \( \sigma \) restricted to \( K_1 \) or to \( K_2 \) is the identity mapping. Therefore a polynomial in elements of \( K_1 \) and \( K_2 \) is fixed by \( \sigma \) and, more generally, \( K_1K_2 \) is fixed by \( \sigma \). Thus

\[ H_1 \cap H_2 = \mathcal{G}(K_1K_2) \implies \mathcal{F}(H_1 \cap H_2) = K_1K_2. \]

If \( \sigma \in H_1 \cup H_2 \), then \( \sigma \) fixes \( K_1 \) or \( \sigma \) fixes \( K_2 \). As \( K_1 \cap K_2 \subset K_1 \), and \( K_1 \cap K_2 \subset K_2 \), \( \sigma \) fixes \( K_1 \cap K_2 \). Hence \( H \subset \mathcal{G}(K_1 \cap K_2) \). If \( H \neq \mathcal{G}(K_1 \cap K_2) \), then \( K_1 \cap K_2 \) is properly contained in \( \mathcal{F}(H) \), hence there exists \( x \in \mathcal{F}(H) \setminus K_1 \cap K_2 \). If \( x \notin K_1 \), then we can find \( \sigma \in H_1 \subset H \) such that \( \sigma(x) \neq x \), hence \( x \notin \mathcal{F}(H) \), a contradiction. We have the same situation if \( x \notin K_2 \) and so \( H = \mathcal{G}(K_1 \cap K_2) \), which implies that \( \mathcal{F}(H) = K_1 \cap K_2 \). \( \square \)

Remark There is no difficulty in extending the above result to \( n \) subgroups and \( n \) subfields for any \( n > 2 \).

We now return briefly to Corollary 6.1. It is easy to deduce that

\[ [KL : F] \leq [K : F][L : F]. \]

However, we do not need the condition on \( K \).

Proposition 6.4 Let \( E \) be a finite extension of \( F \). In addition, let \( K \) and \( L \) be extensions of \( F \) in \( E \). Then

\[ [KL : F] \leq [K : F][L : F], \]

with equality if \([K : F]\) and \([L : F]\) are coprime.
Proof} Let \((\alpha_i)_{i=1}^m\) and \((\beta_j)_{j=1}^n\) be respective bases of \(K\) over \(F\) and \(L\) over \(F\). Then
\[
K = F(\alpha_1, \ldots, \alpha_m), L = F(\beta_1, \ldots, \beta_n) \implies KL = F(\alpha_1, \ldots, \alpha_m, \beta_1, \ldots, \beta_n).
\]
As \(KL = L(\alpha_1, \ldots, \alpha_m)\), we have
\[
[KL : L] \leq m \implies [KL : F] = [KL : L][L : F] \leq mn.
\]
Now suppose that \((m, n) = 1\). As \(m|[KL : F]\) and \(n|[KL : F]\), \(mn|[KL : F]\) and hence the equality.

We say that \(K\) and \(L\) are linearly disjoint over \(F\) if \([K : F]\) and \([L : F]\) are coprime. If this is not the case, then we may have a strict inequality in the equation of the proposition. For example, if \(K \neq F\) and \(K = L\), then
\[
[KL : F] = [K : F] < [K : F][L : F].
\]

If \(K, L\) are linearly disjoint over \(F\) and \((\alpha_1, \ldots, \alpha_m), (\beta_1, \ldots, \beta_n)\) respective bases of \(K\) and \(L\), then a basis of \(KL\) may be found by taking the products \(\alpha_i\beta_j\). Indeed, from Corollary 1.5,
\[
KL = F(\alpha_1, \ldots, \alpha_m, \beta_1, \ldots, \beta_n) = F[\alpha_1, \ldots, \alpha_m, \beta_1, \ldots, \beta_n],
\]
so the elements of \(KL\) are polynomials in the \(\alpha_i\) and \(\beta_j\). However, an expression of the form \(\alpha_1^{s_1} \cdots \alpha_m^{s_m}\) belongs to \(K\), so we may write it as a linear combination (with coefficients in \(F\)) of the \(\alpha_i\). In the same way, we may write an expression of the form \(\beta_1^{t_1} \cdots \beta_n^{t_n}\) as a linear combination of the \(\beta_j\). As a consequence, the elements \(\alpha_i\beta_j\) form a generating set of \(KL\) (as a vector space over \(F\)). Given that there are \(mn\) such elements and that the dimension of \(KL\) over \(F\) is \(mn\), the \(\alpha_i\beta_j\) form a basis of \(KL\).

In Theorem 6.8 we considered the compositum of two extensions of a field, one of which was Galois. We now suppose that \(K\) and \(L\) are both Galois extensions of the field \(F\) contained in a field \(E\). We claim that the compositum \(KL\) is a Galois extension of \(F\). As \(KL\) is a separable extension of \(L\) and a separable extension of \(F\), from Theorem 3.7, \(KL\) is a separable extension of \(F\). Proving that \(KL\) is a normal extension of \(F\) is a little more difficult. First we notice that \(K\) and \(L\) are splitting fields of respectively polynomials \(f\) and \(g\) of \(F[X]\). We have
\[
K = F(\alpha_1, \ldots, \alpha_m) \quad \text{and} \quad L = F(\beta_1, \ldots, \beta_n),
\]
where \(\alpha_1, \ldots, \alpha_m\) (resp. \(\beta_1, \ldots, \beta_n\)) are the roots of \(f\) (resp \(g\)) in \(E\). If \(\gamma_1, \ldots, \gamma_s\) are the distinct elements in the set \(\{\alpha_1, \ldots, \alpha_m, \beta_1, \ldots, \beta_n\}\), then \(KL = F(\gamma_1, \ldots, \gamma_s)\). The polynomial \(fg\) splits in \(KL\). Let \(U \subset KL\) be a splitting field of \(fg\). As \(\gamma_1, \ldots, \gamma_s \in U, F(\gamma_1, \ldots, \gamma_s) \subset U\), i.e., \(KL \subset U\). It follows that \(KL\) is a splitting field of \(fg\) and so a normal extension of \(F\). We have shown that \(KL\) is a Galois extension of \(F\), as claimed.

If \(\sigma \in Gal(KL/F)\), then \(\sigma|_K \in Gal(K/F)\) and \(\sigma|_L \in Gal(L/F)\), because \(K/F\) and \(L/F\) are both normal.

Theorem 6.10 Let us suppose that \(K/F\) and \(L/F\) are both normal. The mapping
\[
\psi : Gal(KL/F) \longrightarrow Gal(K/F) \times Gal(L/F), \sigma \longmapsto (\sigma|_K, \sigma|_L),
\]
is a monomorphism and \(\psi\) is an isomorphism if and only if \(K \cap L = F\).
The mapping $\psi$ is clearly a homomorphism and, if $\sigma \in \text{Gal}(KL/F)$ fixes each element of $K$ and each element of $L$, then $\sigma$ fixes each element of $KL$. Consequently, $\psi$ is a monomorphism.

The mapping $\psi$ is an isomorphism if and only if $[KL:F] = [K:F][L:F]$, which applies only under the condition $[KL:L] = [K:F]$. This is the case if and only if the mapping

$$\phi : \text{Gal}(KL/L) \rightarrow \text{Gal}(K/F), \sigma \mapsto \sigma|_K$$

is an isomorphism. From Theorem 6.8, a necessary and sufficient condition for this is $K \cap L = F$. \(\Box\)

**Remark** We have seen that if $K$ and $L$ are both Galois extensions of $F$, then $KL$ is Galois extension of $F$ and we may consider that the Galois group of $KL$ over $F$ is a subgroup of the direct product of the Galois groups of $K$ and $L$ over $F$. In particular, if the Galois groups $\text{Gal}(K/F)$ and $\text{Gal}(L/F)$ are both abelian, then so is the Galois group $\text{Gal}(KL/F)$.

### 6.3 The fundamental theorem of algebra

It is a well-known that any nonconstant complex polynomial has a complex root. This is the fundamental theorem of algebra. In this section we will give a proof based on the field theory we have developped.

**Proposition 6.5** The field of complex numbers $\mathbb{C}$ has no extension of degree 2.

**Proof** Suppose that $\mathbb{C}$ has an extension $E$ of degree 2. If $\alpha \in E \setminus \mathbb{C}$, then $\deg m(\alpha, F) = 2$. However, every polynomial $f \in \mathbb{C}[X]$ of degree 2 has a complex root, hence $m(\alpha, F)$ is reducible, a contradiction. Hence the result. \(\Box\)

Now we consider extensions of the field of real numbers $\mathbb{R}$.

**Proposition 6.6** $\mathbb{R}$ has no extension of odd degree strictly greater than 1.

**Proof** Suppose that $\mathbb{R}$ has an extension $E$ with odd degree strictly greater than 1. Let $\alpha \in E \setminus \mathbb{R}$. If $\deg m(\alpha, \mathbb{R})$ is odd, then the polynomial $m(\alpha, \mathbb{R})$ has a real root and so is reducible, a contradiction. It follows from Proposition 1.4 that $[\mathbb{R}(\alpha) : \mathbb{R}]$ is even. As

$$[E : \mathbb{R}] = [E : \mathbb{R}(\alpha)][\mathbb{R}(\alpha) : \mathbb{R}],$$

$[E : \mathbb{R}]$ is even. \(\Box\)

We are now in a position to prove the fundamental theorem of algebra.

**Theorem 6.11** If $f \in \mathbb{C}[X]$ is nonconstant, then $f$ has a root in $\mathbb{C}$.

**Proof** We will first prove the result for a nonconstant polynomial $f \in \mathbb{R}[X]$. We note $g(X) = (1 + X^2)f(X) \in \mathbb{R}[X]$ and let $E$ be a splitting field of $g$. The complex numbers $\pm i$ and $\mathbb{R}$ belong to $E$ so $\mathbb{C}$ is contained in $E$. As the characteristic of $\mathbb{R}$ is 0, $g$ is separable and so $E$ is separable (see Theorem 3.8). Therefore $E$ is a Galois extension of $\mathbb{R}$. We now set $G = \text{Gal}(E/\mathbb{R})$, i.e., $G$ is the Galois group of $g$. If $|G| = 2^m$, with $m$ odd, then $G$ has a (Sylow-)subgroup $H$ of order $2^s$. We set $K = F(H)$. Then, from Theorem 6.6,

$$[K : \mathbb{R}] = [G : H] = m.$$
As \( m \) is odd and \( R \) has no extension of odd degree strictly greater than 1, \( m = 1 \). Thus \( G \) is a 2-group.

We now set \( H' = Gal(E/C) \) (the Galois group of \( g \) considered as a member of \( C[X] \)). As \( H' \) is a subgroup of \( G \), \( H' \) is a 2-group. If \( |H'| = 2^t \), with \( t \geq 1 \), then \( H' \) has a subgroup \( H'' \) of index 2. If \( K'' = F(H'') \), then

\[
[K'':C] = [H'':H''] = 2,
\]

which contradicts Proposition 6.5. It follows that \( H' = \{id\} \) and \( E = C \) and so all the roots of \( g \), and hence of \( f \), lie in \( C \).

We now consider polynomials \( f \in C[X] \setminus R[X] \). If we set \( g = \bar{f}f \), where \( \bar{f} \) is the polynomial whose coefficients are the complex conjugates of those of \( f \), then \( g \in R[X] \). If \( \alpha \) is a root of \( g \), then \( \alpha \) is a root of \( \bar{f} \) or of \( f \). This implies that \( \alpha \) or \( \bar{\alpha} \) is a root of \( f \). Hence \( f \) has a root in \( C \).

This ends the proof. \( \square \)

### 6.4 Normal closures

In this short section we give a useful characterization of the normal closure \( N \) of \( E \) over \( F \) in the case where \( E \) is a finite extension of \( F \). In Section 5.1 we saw that, if \( E = F(\alpha_1, \ldots, \alpha_n) \) and \( m_1(X) = m(\alpha_i, F) \), then a splitting field of \( m(X) = m_1(X) \cdots m_n(X) \) is a normal closure \( N \) of \( E \) over \( F \). We recall that if \( L_1 \) and \( L_2 \) are subfields of a field \( E \), then \( L_1L_2 \) is the smallest subfield of \( E \) containing both \( L_1 \) and \( L_2 \). More generally, if \( L_1, \ldots, L_s \) are subfields of \( E \), then \( L_1L_2 \cdots L_s \) is the smallest subfield of \( E \) containing the \( L_i \).

**Theorem 6.12** Let \( E \) be a finite extension of \( F \) and \( N \) the normal closure of \( E \) over \( F \) in an algebraic closure \( C \) of \( E \). Then

\[
N = \prod_{\sigma \in Gal(N/F)} \sigma(E).
\]

**Proof** We use the description of \( N \) as the splitting field of \( m = m_1 \cdots m_n \) seen above. If \( \sigma \in Gal(N/F) \), then \( \sigma(F) = F \) and \( \sigma(\alpha_i) \in N \), for all \( i \), because the \( \sigma(\alpha_i) \) are roots of \( m \). Hence \( \sigma(E) \subset N \), for all \( \sigma \in Gal(N/F) \) and so

\[
\prod_{\sigma \in Gal(N/F)} \sigma(E) \subset N.
\]

If \( \alpha \in N \) is a root of \( m \), then \( \alpha \) is a root of \( m_i \), for some \( i \). From Proposition 2.3, we know that there is an \( F \)-isomorphism \( \tau : F(\alpha) \rightarrow F(\alpha) \), with \( \tau(\alpha_i) = \alpha \). Using Theorem 2.7, we may extend \( \tau \) to a monomorphism \( \sigma \) from \( N \) into \( C \). As \( N \) is a normal extension, we know from Proposition 5.2 that \( \sigma \) is an automorphism of \( N \), i.e., \( \sigma \in Gal(N/F) \). Given that \( \alpha_i \in E \) and \( \sigma(\alpha_i) = \alpha \), we have \( \alpha \in \sigma(E) \). It follows that

\[
\alpha \in \prod_{\sigma \in Gal(N/F)} \sigma(E) \Rightarrow N \subset \prod_{\sigma \in Gal(N/F)} \sigma(E).
\]

This ends the proof. \( \square \)

Chapter 7

The Galois group of a polynomial

In this chapter we continue our study of the Galois group. If \( f \) is a polynomial with coefficients in the field \( F \) and \( E \) a splitting field of \( f \), then we call \( \text{Gal}(E/F) \) a Galois group of the polynomial \( f \). As splitting fields of a polynomial are isomorphic, any two Galois groups of a polynomial are isomorphic, so we often, with an abuse of language, speak of the Galois group of a polynomial.

**Proposition 7.1** If \( E \) is a splitting field of a separable polynomial \( f \in F[X] \), then \( E \) is a Galois extension of \( F \).

**proof** From Theorem 2.1 we know that the extension \( E \) is finite. Being a splitting field of a polynomial, we also know that it is normal, so we only need to show that \( E \) is separable. Now, \( E = F(\alpha_1, \ldots, \alpha_n) \), where the \( \alpha_i \) are the roots of \( f \). Each minimal polynomial \( m_i = m(\alpha_i, F) \) divides an irreducible factor of \( f \). As the irreducible factors of \( f \) do not have multiple roots, no \( m_i \) has a multiple root. Thus each \( \alpha_i \) is separable. From Theorem 3.8, \( F(\alpha_1, \ldots, \alpha_n) \) is separable.

**Corollary 7.1** If \( G = \text{Gal}(E/F) \) is the Galois group of a separable polynomial, then 
\[ |G| = [E : F]. \]

**proof** It is sufficient to apply Theorem 6.1.

Different polynomials over the same field may have the same Galois group. This may be useful in determining the Galois group of a given polynomial. For example, if \( f \in F[X] \) has the splitting field \( E \) and \( a \in F \), then \( E \) is also the splitting field of \( g(X) = f(-a + X) \) : if \( \alpha_1, \ldots, \alpha_n \) are the roots of \( f \) in \( E \), then \( a + \alpha_1, \ldots, a + \alpha_n \) are the roots of \( g \) in \( E \). The following result is useful, because certain methods of determining the Galois group only apply to monic polynomials with integer coefficients.

**Proposition 7.2** If \( f \in \mathbb{Q}[X] \), then there is a strongly separable monic polynomial \( g \in \mathbb{Z}[X] \) with the same Galois group over \( \mathbb{Q} \) as \( f \).

**proof** Let \( E \) be the splitting field of \( f \in \mathbb{Q}[X] \) in \( \mathbb{C} \). If we set \( f_1 = \frac{f}{\text{gcd}(f,f')} \), then \( f_1 \) has the same roots as \( f \) and these roots are simple. Therefore \( f_1 \) is strongly separable and has the same splitting field as \( f \).

Now let \( u \) be the lcm of the denominators of the coefficients of \( f_1 \). If we set \( f_2 = uf_1 \), then \( f_2 \in \mathbb{Z}[X] \) and has the same roots as \( f_1 \).
Finally, if \( f_2(X) = \sum_{i=0}^{n} a_i X^i \), then we set
\[
g(Y) = \sum_{k=0}^{n-1} a_k (a_n)^{n-k-1} Y^k + Y^n \in \mathbb{Z}[X].
\]
As
\[
g(a_n X) = a_n^{-1} f_2(X),
\]
g has the same roots as \( f \) up to multiplication by the constant \( a_n \) and so has the same splitting field as \( f_2 \). Thus we have found a monic strongly separable polynomial in \( \mathbb{Z}[X] \) with splitting field \( E \).

By Cayley’s theorem, any finite group of cardinal \( k \) can be identified with a subgroup of \( S_k \), the group of permutations of the set \( \mathbb{N}_k = \{1, \ldots, k\} \). In general, a Galois group \( G \) of a polynomial can be identified with a subgroup of a group of permutations \( S_n \), where \( n \) is much smaller that the cardinal of the group.

**Proposition 7.3** If \( f \in F[X] \) has \( n \) distinct roots in a splitting field, then the Galois group of \( f \) is isomorphic to a subgroup of \( S_n \).

**Proof** We set \( A = \{a_1, \ldots, a_n\} \) the set of roots of \( f \) in a splitting field \( E \). If \( \sigma \in \text{Gal}(E/F) \), then \( \sigma \) permutes the roots of \( f \), so we may define a mapping
\[
\phi : \text{Gal}(E/F) \to S_A, \sigma \mapsto \sigma|_A,
\]
where \( S_A \) denotes the group of permutations on \( A \). The mapping \( \phi \) is clearly a group homomorphism. The \( F \)-automorphism \( \sigma \) is determined by its effect on the roots of \( f \), so \( \phi \) is injective. Thus \( \text{Gal}(E/F) \) is isomorphic to a subgroup of \( S_A \). As \( S_A \) is isomorphic to \( S_n \), \( \text{Gal}(E/F) \) is isomorphic to a subgroup \( G \) of \( S_n \).

We have assumed a certain order on the roots of the polynomial. It is natural to ask what happens when we change the order. Suppose that we choose a different ordering of the roots:
\[
A = \{a'_1, \ldots, a'_n\}.
\]
We obtain an isomorphism \( \phi' \) of the Galois group \( \text{Gal}(E/F) \) onto another subgroup \( G' \) of \( S_n \). If \( \sigma \in \text{Gal}(E/F) \), \( \phi' (\sigma) = s \) and \( \phi'(\sigma) = s' \), then
\[
\sigma(a_i) = a_{s(i)} \quad \text{and} \quad \sigma(a'_{i}) = a'_{s'(i)},
\]
for \( i = 1, \ldots, n \). There is a unique permutation \( r \in S_n \) such that \( a'_{i} = a_{r(i)} \), for all \( i \), hence we can write
\[
a_{sr(i)} = \sigma(a_{r(i)}) = \sigma(a'_{i}) = a'_{s'(i)} = a_{rs'(i)}.
\]
Therefore, for all \( i \),
\[
sr(i) = rs'(i) \implies r^{-1}sr = s' \implies G' = r^{-1}Gr,
\]
i.e., \( G' \) is a conjugate of \( G \).

**The general polynomial**

The general polynomial of degree \( n \) over a field \( F \) is
\[
f(Y) = Y^n - X_1 Y^{n-1} + X_2 Y^{n-2} - \cdots + (-1)^{n-1} X_{n-1} + (-1)^n X^n \in F(X_1, \ldots, X_n)[Y],
\]
where \( F(X_1, \ldots, X_n) \) is the rational function field over the field \( F \) in \( n \) variables. It is not difficult to determine the Galois group of \( f \).
Theorem 7.1 The Galois group of the general polynomial \( f \) is the symmetric group \( S_n \).

**Proof** Let \( L = F(X_1, \ldots, X_n) \). Then \( f \in L[Y] \). Now let \( Z_1, \ldots, Z_n \) be the roots of \( f \) in some extension of \( L \). Then \( X_i = s_i(Z_1, \ldots, Z_n) \), where \( s_i \) is the \( i \)th elementary symmetric polynomial. Hence \( L = F(s_1(Z_1, \ldots, Z_n), \ldots, s_n(Z_1, \ldots, Z_n)) \) and a splitting field of \( f \) is given by

\[
L(Z_1, \ldots, Z_n) = F(s_1(Z_1, \ldots, Z_n), \ldots, s_n(Z_1, \ldots, Z_n), Z_1, \ldots, Z_n) = F(Z_1, \ldots Z_n).
\]

Therefore

\[
Gal_L(f) \simeq Gal(F(Z_1, \ldots, Z_n)/F(s_1, \ldots, s_n)) \simeq Gal(F(Z_1, \ldots, Z_n)/F_S(Z_1, \ldots, Z_n)) = S_n,
\]

according to the discussion after Theorem 6.7. \( \square \)

7.1 Irreducible polynomials

Before studying the particular properties of Galois groups of irreducible polynomials, we will revise the notion of the *action of a group* on a set. We recall that a group \( G \), with identity \( e \), acts on a set \( X \) if there is a mapping \( \Phi : G \times X \to X \), called an action and usually written \( \Phi(g, x) = g.x \), such that

- \( e.x = x \), for all \( x \in X \);
- \( (gh).x = g.(h.x) \), for all \( g, h \in G \) and \( x \in X \).

(We sometimes refer to the action we have just defined as a left action to distinguish it from a right action, where we replace the second condition by the following:

\[
(gh).x = h.(g.x),
\]

for all \( g, h \in G \) and \( x \in X \). Of course, if the group \( G \) is abelian, then there is no distinction between left and right actions.)

The orbit of an element \( x \in X \), written \( O_x \), is the collection of \( y \in X \) for which there exists \( g \in G \) with \( y = g.x \). We define a relation \( R \) on \( X \) by \( xRy \) if \( y \in O_x \). Then \( R \) is an equivalence relation on \( X \) and the distinct orbits are its equivalence classes. We say that the action is *transitive* if there is a unique orbit, i.e., for any \( x, y \in X \), there is a \( g \in G \), with \( g.x = y \). The action is *free* if \( g.x = x \) implies that \( g \) is the identity of \( G \).

If \( x \in X \), then the *stabilizer of \( x \)*, which we write \( G_x \), is the set of elements of \( G \) which leave \( x \) unchanged:

\[
G_x = \{ g \in G : g.x = x \}.
\]

Clearly \( G_x \) is a subgroup of \( G \). The following result is known as the orbit-stabilizer theorem.

**Theorem 7.2** If \( G \) is finite and \( x \in X \), then

\[
|O_x| = [G : G_x] = \frac{|G|}{|G_x|}.
\]
proof We define a mapping \( \phi : G \rightarrow O_x, g \mapsto g.x. \) 
\( \phi \) is clearly surjective. As \( G_x \) is a subgroup of \( G \),
\[ \phi(g) = \phi(h) \iff g.x = h.x \iff g^{-1}h \in G_x. \]
Therefore we have a well-defined bijection \( \tilde{\phi} : G/G_x \rightarrow O_x \) defined by 
\[ \tilde{\phi}(gG_x) = \phi(g). \]
It follows that
\[ |O_x| = [G : G_x] = \frac{|G|}{|G_x|}. \]
This ends the proof. 

If \( f \in F[X] \) is separable, \( A = \{ \alpha_1, \ldots, \alpha_n \} \) the roots of \( f \) in a splitting field \( E \) and \( G = \text{Gal}(E/F) \), then the mapping
\[ \Phi : G \times A, (\sigma, \alpha_i) \mapsto \sigma(\alpha_i) \]
defines an action of \( G \) on \( A \). (As the Galois group \( G \) of a polynomial of degree \( n \) is isomorphic to a subgroup \( H \) of \( S_n \), we may consider that \( G \) acts on \( N_n \).) For irreducible, separable polynomials we can say more.

Theorem 7.3 Let \( f \) be a separable polynomial in \( F[X] \) of degree \( n \) with Galois group \( G = \text{Gal}(E/F) \). If \( f \) is irreducible, then
\begin{itemize}
  \item a. \( n \) divides the order of \( G \);
  \item b. the action of \( G \) on \( A \) is transitive.
\end{itemize}

proof a. Let \( \alpha \in E \) be a root of \( f \). From Proposition 1.4 we have \([F(\alpha) : F] = n\). Now \([F(\alpha) : F][E : F]\). In addition, \( E \) is a Galois extension of \( F \) and so, from Corollary 7.1, \([E : F] = |G|\). Therefore \( n \) divides \(|G|\).

b. Let \( f \in F[X] \) be irreducible and \( \alpha, \alpha' \) two roots of \( f \) in \( E \). From Proposition 2.3, with \( F^* = F \) and \( \sigma = \text{id}_F \), we obtain an isomorphism \( \sigma' \) from \( F(\alpha) \) onto \( F(\alpha') \) extending \( \text{id}_F \) such that \( \sigma'(\alpha) = \alpha' \). We now apply Theorem 2.2 to obtain \( \sigma \in \text{Gal}(E/F) \) taking \( \alpha \) to \( \alpha' \). This implies that the action of the Galois group on \( A \) is transitive. 

Remark We recall that a group of permutations \( G \) on a set \( X \) is said to be transitive if for any pair \((x, y) \in X^2\), there exists \( \pi \in G \) such that \( \pi(x) = y \). Thus, if \( f \) is irreducible, then \( G|_A \) is a transitive permutation group.

The second part of the theorem which we have just proved has a partial converse.

Proposition 7.4 Let \( f \in F[X] \), with \( \deg f \geq 2 \), and \( G \) be its Galois group. If \( f \) has two distinct irreducible factors, then the action of \( G \) on \( A \) is not transitive.

proof Let \( \alpha_1, \alpha_2 \) be roots of \( f \) and \( g_1, g_2 \) be distinct irreducible factors of \( f \), with \( g_1(\alpha_1) = g_2(\alpha_2) = 0 \). If \( \sigma \in G \) and \( \sigma(\alpha_1) = \alpha_2 \), then 
\[ g_1(\alpha_2) = g_1(\sigma(\alpha_1)) = \sigma(g_1(\alpha_1)) = 0. \]
We may suppose that \( g_1 \) and \( g_2 \) are monic polynomials. Then both \( g_1 \) and \( g_2 \) are minimal polynomials of \( \alpha_2 \), which is impossible. Therefore the action of \( G \) on \( A \) is not transitive. \( \square \)

**Remark** If \( f = \lambda g^m \), where \( \lambda \in F \), \( g \in F[X] \) is irreducible and \( m \geq 2 \), then the action of \( G \) on \( A \) is transitive. It is sufficient to notice that a splitting field of \( g \) is a splitting field of \( f \) and then apply the second part of Theorem 7.3.

### 7.2 Cyclotomic extensions

We consider the polynomial \( f(X) = -1 + X^n \in F[X] \). The roots of this equation in a splitting field are called \( n \)th roots of unity. If \( \text{char } F = 0 \) or \( \text{char } F = p > 0 \), with \( (p,n) = 1 \), then \( f \) is separable:

\[
f'(X) = nX^{n-1} \implies \gcd(f,f') = 1.
\]

In this case, \( f \) has \( n \) distinct roots in a splitting field \( E \). The set of these roots, which we will note \( \mu_n \), form a subgroup of the multiplicative group of \( E \). As \( \mu_n \) is finite, by Theorem 3.3, \( \mu_n \) is cyclic. A generator \( \zeta \) of this group is said to be a *primitive* \( n \)th root of unity. An extension \( E = F(\zeta) \), where \( \zeta \) is a primitive \( n \)th root of unity is called a cyclotomic extension of \( F \). In fact, \( E \) is a splitting field of the polynomial \( f(X) = -1 + X^n \), so we have \( E = F(\mu_n) \) and it follows that \( E \) is a Galois extension of \( F \). Clearly, if \( \zeta' \) is another primitive \( n \)th root of unity, then \( E = F(\zeta') \). We write \( \mu_n^* \) for the subset of \( \mu_n \) composed of primitive \( n \)th roots of unity. The cardinal of \( \mu_n^* \) is \( \phi(n) \), where \( \phi \) is Euler’s totient function.

**Exercise 7.1** Show that, if \( \text{char } F = p > 0 \) and \( (p,n) \neq 1 \), then there is no primitive \( n \)th root of unity.

Up to now we have assumed that \( \text{char } F = 0 \), or \( \text{char } F = p > 0 \) with \( (p,n) = 1 \). In this section we will continue to do so. We consider the Galois group of the cyclotomic extension \( F(\mu_n) \).

**Proposition 7.5** If \( \sigma \in \text{Gal}(F(\mu_n)/F) \), then there is an integer \( a = a(\sigma) \), with \( (a,n) = 1 \), such that \( \sigma(x) = x^a \), for all \( x \in \mu_n \).

**Proof** Let \( \zeta \) be a generator of \( \mu_n \). Then

\[
\sigma(\zeta)^n = \sigma(\zeta^n) = \sigma(1) = 1
\]

and, for \( j = 1, \ldots, n-1 \),

\[
\sigma(\zeta^j) = \sigma(\zeta^j) \neq 1,
\]

because \( \zeta^j \neq 1 \) and \( \sigma \) is injective. Hence \( \sigma(\zeta) \) is also a generator of \( \mu_n \). This implies that \( \sigma(\zeta) = \zeta^a \), where \( (a,n) = 1 \). Now take any \( x \in \mu_n \). There exists an integer \( k \) such that \( x = \zeta^k \), so

\[
\sigma(x) = \sigma(\zeta^k) = \sigma(\zeta)^k = (\zeta^a)^k = (\zeta^k)^a = x^a,
\]

which is what we set out to prove. \( \square \)

We may define a mapping \( \phi \) from \( \text{Gal}(F(\mu_n)/F) \) into \( \mathbb{Z}_n^* \), the group of units of \( \mathbb{Z}_n \), by setting \( \phi(\sigma) = [a(\sigma)] \), where \( [u] \) denotes the congruence class modulo \( n \) of \( u \).

**Theorem 7.4** The mapping \( \phi \) is a monomorphism.
proof Let \( \sigma \) and \( \tau \) be elements of \( \text{Gal}(F(\mu_n)/F) \) and \( \zeta \) a primitive \( n \)th root of unity. Then
\[
(\sigma \tau)(\zeta) = \sigma(\tau(\zeta)) = \sigma(\zeta^a) = \sigma(\zeta)^a = (\zeta^{a_\sigma})^{a_\tau} = \zeta^{a_\sigma a_\tau}.
\]
In addition, \((\sigma \tau)(\zeta) = \zeta^{a_\sigma a_\tau}\) and it follows that \( a(\sigma \tau) \equiv a(\sigma) a(\tau) \pmod{n} \). Therefore
\[
[a(\sigma \tau)] = [a(\sigma)] [a(\tau)] \implies \phi(\sigma \tau) = \phi(\sigma) \phi(\tau).
\]
We have shown that \( \phi \) is a homomorphism. It remains to establish the injectivity. If \( \sigma \) is in the kernel of \( \phi \), then \( a(\sigma) = 1 \) and so \( \sigma(\zeta) = \zeta \). As \( \sigma \) fixes all the elements of \( F \), \( \sigma \) is the identity on \( F(\mu_n) \), i.e., \( \phi \) is injective. \( \square \)

Corollary 7.2 If \( E \) is a cyclotomic extension of \( F \), then the Galois group \( G = \text{Gal}(E/F) \) is abelian.

proof As \( G \) is isomorphic to a subgroup of \( \mathbb{Z}_n^* \), which is abelian, \( G \) is abelian. \( \square \)

Remark The Galois group of a cyclotomic extension may be cyclic. This is so if \( n = 2^k \), with \( k = 1, 2 \), or \( n = p^k \), where \( p \) is an odd prime and \( k \in \mathbb{N}^* \), because in these cases the group \( \mathbb{Z}_n^* \) is cyclic (see [21], for example).

Exercise 7.2 Let \( n = 5 \) or \( n > 6 \). Show that the injection of \( \text{Gal}(\mathbb{R}(\mu_n)/\mathbb{R}) \) in \( \mathbb{Z}_n^* \) is not surjective.

It is interesting to consider composita of cyclotomic extensions. To do so we will need a little elementary group theory.

Theorem 7.5 Let \( G \) be a group, with identity \( e \), and \( x, y \) elements of \( G \) which commute. If \( o(x) = m, o(y) = n \) and \( (m, n) = 1 \), i.e., \( m \) and \( n \) are coprime, then \( o(xy) = mn \).

proof We first notice that \( \langle x \rangle \cap \langle y \rangle = \{ e \} \). By Lagrange’s theorem, \( |\langle x \rangle \cap \langle y \rangle| \) divides both \( m \) and \( n \). As \( (m, n) = 1 \), we have \( \langle x \rangle \cap \langle y \rangle = \{ e \} \). Now,
\[
(xy)^mn = (x^m)^n(y^n)^m = ee = e.
\]
On the other hand, if \( (xy)^k = e \), then \( x^k = y^{-k} \) and so \( x^k \in \langle x \rangle \cap \langle y \rangle \). Hence, \( x^k = e \), which implies that \( m|k \). In the same way, we have \( n|k \). It follows that \( mn|k \); because \( (m, n) = 1 \) and so \( o(xy) = mn \). \( \square \)

It would be natural to assume that if \( x \) and \( y \) commute then \( o(xy) = [m, n] \). However, this is not true. We only need to consider the case where \( y = x^{-1} \) and \( x \neq e \); then \( o(xy) = o(e) = 1 \) and \( [m, n] = [m, m] > 1 \). On the other hand, we have a result which is quite close to the statement we have just considered. It follows from the theorem.

Corollary 7.3 Let \( G \) be a group, with identity \( e \), and \( x, y \) elements of \( G \) which commute. If \( o(x) = m, o(y) = n \), then there are powers \( a \) of \( x \) and \( b \) of \( y \) such that \( o(x^a y^b) = [m, n] \).

proof If \( p_1, \ldots, p_s \) are the primes in the decomposition of \( m \) and \( n \) and \( m = \prod_{i=1}^s p_i^{\alpha_i} \) and \( n = \prod_{i=1}^s p_i^{\beta_i} \), then \( [m, n] = \prod_{i=1}^s p_i^{m_i} \), where \( m_i = \max(\alpha_i, \beta_i) \). We divide the indices \( i \) into two distinct classes, \( I \) being composed of those \( i \) for which \( \alpha_i = m_i \) and \( J \) of those indices for which \( \beta_i = m_i > \alpha_i \). We set
\[
m' = \prod_{i\in I} p_i^{m_i} \quad \text{and} \quad n' = \prod_{i\in J} p_i^{m_i}.
\]

59
Clearly $[m', n'] = [m, n]$. We also notice that $m'|m$, $n'|n$ and
\[ o(x^{m'}) = m', \quad o(y^{n'}) = n' \quad \text{and} \quad (m', n') = 1, \]

hence, by Theorem 7.5,
\[ o(x^{m'} y^{n'}) = m' n' = [m, n], \]

which completes the proof.

We now consider the compositum of two cyclotomic fields.

**Proposition 7.6** The compositum of the fields $F(\mu_m)$ and $F(\mu_n)$ is $F(\mu_{[m,n]})$.

**Proof** Because $[m, n]$ is a multiple of $m$ and $n$, both the fields $F(\mu_m)$ and $F(\mu_n)$ are included in $F(\mu_{[m,n]})$, hence the compositum of these two fields is also included in $F(\mu_{[m,n]})$. Now let $\zeta_m$ (resp. $\zeta_n$) be an $m$th (resp. $n$th) primitive root of unity. From Corollary 7.3, there are powers $a$ of $\zeta_m$ and $b$ of $\zeta_n$ such that $o(\zeta_m^a \zeta_n^b) = [m, n]$, which implies that a primitive $[m, n]$th root of unity lies in the compositum $F(\mu_m)F(\mu_n)$. Therefore $F(\mu_{[m,n]}) \subset F(\mu_m)F(\mu_n)$. We thus have the equality we were looking for.

**Remark** We might be tempted to think that $F(\mu_m) \cap F(\mu_n) = F(\mu_{[m,n]})$. As $m$ and $n$ are both multiples of $(m, n)$, we certainly have $F(\mu_{(m,n)}) \subset F(\mu_m) \cap F(\mu_n)$, however the other inclusion may not be true. Here is an example. We set $F = \mathbb{Q}(\sqrt{3})$ and we consider $F(\mu_3)$ and $F(\mu_4)$. As $(3, 4) = 1$, $F(\mu_{(3,4)}) = F(1) = F$. On the other hand,
\[ F(\mu_4) = \mathbb{Q}(\sqrt{3}, i) = F(\mu_3) \implies F(\mu_3) \cap F(\mu_4) = \mathbb{Q}(\sqrt{3}, i) \neq F. \]

With more knowledge of the field $F$ we can say more about cyclotomic extensions. We will first consider the case where $F = \mathbb{Q}$. To do so we will introduce cyclotomic polynomials.

**Exercise 7.3** Let $F$ be field and $\xi_1$ (resp. $\xi_2$) an $m$th (resp. $n$th) root of unity. Show that the compositum $F(\xi_1)F(\xi_2)$ is included in the cyclotomic field $F(\mu_{[m,n]})$.

### 7.3 Cyclotomic polynomials

In this section we will be concerned with a class of polynomials with coefficients in $\mathbb{Q}$. The $n$th cyclotomic polynomial $\Phi_n \in \mathbb{C}[X]$ is defined by
\[ \Phi_n(X) = \prod_{\zeta \in \mu_n^*} (-\zeta + X). \]

The degree of $\Phi_n$ is $\phi(n)$, because $|\mu_n^*| = \phi(n)$.

If $z \in \mu_n$, then $o(z)|n$, hence $z \in \bigcup_{d|n} \mu_d^*$. On the other hand, if $d|n$ and $z \in \mu_d^*$, then $z \in \mu_n$. Thus $\mu_n = \bigcup_{d|n} \mu_d^*$. As $\mu_d^* \cap \mu_{d'}^* = \emptyset$, if $d \neq d'$, the sets $\mu_d^*$, with $d|n$, form a partition of $\mu_n$ and
\[ -1 + X^n = \prod_{d|n} \left( \prod_{z \in \mu_d^*} (-z + X) \right) = \prod_{d|n} \Phi_d. \]

In fact, all the coefficients of $\Phi_n$ are integers.
Proposition 7.7 The polynomial $\Phi_n$ belongs to $\mathbb{Z}[X]$ and is monic; in addition, its first coefficient is 1, if $n \geq 2$.

Proof From the definition of $\Phi_n$, it is clearly monic. We now prove by induction that $\Phi_n \in \mathbb{Z}[X]$ and also that the constant term of the polynomial is 1, if $n \geq 2$. As $\Phi_1(X) = -1 + X$ and $\Phi_2(X) = 1 + X$, the claim is true for $n = 1$ and $n = 2$. Suppose now that it is true up to $n - 1$, with $n > 2$, and consider the case $n$. We have

$$-1 + X^n = \left( \prod_{d|n, d < n} \Phi_d \right) \Phi_n = A \Phi_n.$$

If $A(X) = \sum_{i=0}^{\phi(n)} a_i X^i$ and $\Phi_n(X) = \sum_{j=0}^{\phi(n)} b_j X^j$, then $a_i \in \mathbb{Z}$, for all $i$ and $a_0 = -1$. As $a_0 b_0 = -1$, we have $b_0 = 1$. Also,

$$a_0 b_1 + a_1 b_0 = -b_1 + a_1 = 0 \implies b_1 = a_1 \in \mathbb{Z}.$$

In addition, as

$$a_0 b_2 + a_1 b_1 + a_2 b_0 = -b_2 + a_1 b_1 + a_2 = 0 \implies b_2 = a_1 b_1 + a_2 \in \mathbb{Z}.$$ 

Continuing in the same way, we see that $b_j \in \mathbb{Z}$, for all $j$. \qed

Exercise 7.4 Show that, if $p$ is a prime number and $r \in \mathbb{N}^*$, then $\Phi_{p^r}(X) = \Phi_p(X^{p^r-1})$.

We have seen that the coefficients of a cyclotomic polynomial are integers. We can say more. In particular, any integer figures as a coefficient of at least one cyclotomic polynomial. A proof of this may be found in [17]. For $n \geq 3$, the degree is even so there is a middle coefficient. If $n$ is a power of 2, then this coefficient is 0; otherwise it is an odd number. This is proved in [7].

We may thus consider the polynomials $\Phi_n$ as members of $\mathbb{Z}[X]$. We will now show that they are irreducible over $\mathbb{Q}$. However, we need some preliminary results.

If $f$ is a polynomial in $\mathbb{Z}[X]$ and $p$ a prime number, then we may define $\overline{f} \in F_p[X]$ by replacing the coefficients of $f$ by their congruence classes modulo $p$. The polynomial $\overline{f}$ so obtained is called the reduction modulo $p$ of $f$. Clearly, if $f = AB$, then $\overline{f} = \overline{A} \overline{B}$. The next result needs a proof.

Lemma 7.1 Let $F$ be a field and $A, B \in F[X]$, with $A$ irreducible. If $A$ and $B$ have a common root, then $A$ divides $B$.

Proof Let $\alpha$ be a common root of $A$ and $B$. If $A$ does not divide $B$, then $A$ and $B$ are coprime and so there exist $S, T \in F[X]$ such that

$$SA + TB = 1 \implies S(\alpha)A(\alpha) + T(\alpha)B(\alpha) = 1,$$

which is a contradiction, because $\alpha$ is a root of $A$ and $B$. Hence $A$ divides $B$. \qed

Lemma 7.2 If $p$ is a prime number and $A_1, \ldots, A_n \in F_p[X]$, then $(\sum_{i=1}^{n} A_i)^p = \sum_{i=1}^{n} A_i^p$. Also, if $A(X) \in F_p[X]$, then $A(X)^p = A(X^p)$.
PROOF As char $F_p[X] = p$ and $p|(p_i)$, for $i = 1, \ldots, p - 1$, we have $(A_1 + A_2)^p = A_1^p + A_2^p$. An induction argument allows us to obtain the result for any $n$.

If $A(X) = \sum_{i=0}^{m} a_i X^i$, then from the first part of the proof,

$$A(X)^p = \sum_{i=0}^{m} (a_i X^i)^p = \sum_{i=0}^{m} a_i^p X^{ip} = A(X^p).$$

This ends the proof. \qed

Before turning to the proof of the irreducibility of cyclotomic polynomials, we recall the following result, which follows from Gauss’s lemma:

If $A \in \mathbb{Z}[X]$ and $A = BC$, with $B, C \in \mathbb{Q}[X]$ and monic, then $B, C \in \mathbb{Z}[X]$.

**Theorem 7.6** For all $n \in \mathbb{N}^*$, the polynomial $\Phi_n$ is irreducible over $\mathbb{Q}$.

**Proof** Let $A$ be a monic, irreducible polynomial in $\mathbb{Q}[X]$, which divides $\Phi_n$. If $\alpha \in \mathbb{C}$ is a root of $A$, then $\alpha$ is also a root of $\Phi_n$ and so a primitive $n$th root of unity.

As $A$ divides $\Phi_n$ and $\Phi_n$ divides $f(X) = -1 + X^n$, there exists $B \in \mathbb{Q}[X]$ such that $AB = f$. As $A$ is monic, so is $B$. Now using the result cited before the statement of the theorem, we see that $A, B \in \mathbb{Z}[X]$. In addition, $A$ and $B$ are coprime. (If this were not the case, then $A$ and $B$ would have a common root and their product at most $n - 1$ distinct roots, a contradiction.)

Let $p$ be a prime number such that $p < n$ and $p \nmid n$. We will show that $\alpha^p$ is a root of $A$. If this is not the case, then $\alpha^p$ is a root of $B$. (As $\alpha$ is a root of $f$, any power of $\alpha$ is also a root of $f$, hence of $A$ or $B$.) It follows that $\alpha$ is a root of $B(X^p)$. From Lemma 7.1, we have $A(X) | B(X^p)$. Taking reductions modulo $p$, we obtain $A(X) | \bar{B}(X^p)$. If $C \in F_p[X]$ is irreducible, then, using Lemma 7.2,

$$C(X) | \bar{A}(X) \implies C(X) | \bar{B}(X^p) \implies C(X) | \bar{B}(X) \implies C(X) | \bar{B}(X).$$

Hence $\bar{A}$ and $\bar{B}$ are not coprime in $\mathbb{Z}_p[X]$. However, $A$ and $B$ are coprime, so we have a contradiction. It follows that $\alpha^p$ is a root of $A$, and also a primitive $n$th root of unity.

If $1 < s < n$ is coprime with $n$ and has the prime factorization $s = p_1 \cdots p_k$, then all the $p_i$ are prime with $n$. From what we have just seen, $\alpha^{p_i}$ is a root of $A$, and also a primitive $n$th root of unity. Replacing $\alpha$ by $\alpha^{p_i}$ we obtain that $\alpha^{p_1 \cdots p_2}$ is a root of $A$ and also a primitive $n$th root of unity. Continuing in the same way, we see that $\alpha^s$ is a root of $A$ and also a primitive $n$th root of unity. It follows that all the primitive $n$th roots of unity are roots of $A$ and therefore $A = \Phi_n$, i.e., $\Phi_n$ is irreducible. \qed

**Corollary 7.4** The cyclotomic polynomial $\Phi_n$ is the minimal polynomial over $\mathbb{Q}$ of each primitive $n$th root $\zeta$ of unity, i.e., $m(\zeta, \mathbb{Q}) = \Phi_n$.

**Exercise 7.5** Show that the polynomial

$$P_n(X) = 1 + X + \cdots + X^n \in \mathbb{Q}[X]$$

is irreducible if and only if $n + 1$ is a prime number.
7.4 Cyclotomic extensions of the rationals

We now consider the Galois group of certain polynomials in $\mathbb{Q}[X]$, namely the cyclotomic polynomials.

**Theorem 7.7** The Galois group $G = \text{Gal}(\mathbb{Q}(\mu_n)/\mathbb{Q})$ is isomorphic to $\mathbb{Z}_n^\times$.

**Proof** From Theorem 7.4 we know that $G$ is isomorphic to a subgroup of $\mathbb{Z}_n^\times$. However, if $\zeta$ is a primitive $n$th root of unity, then

$$|G| = [\mathbb{Q}(\zeta) : \mathbb{Q}] = \deg \Phi_n = \phi(n).$$

The second equality comes from Corollary 7.4. As $|\mathbb{Z}_n^\times| = \phi(n)$ and $\mathbb{Q}(\mu_n) = \mathbb{Q}(\zeta)$, $G$ is isomorphic to $\mathbb{Z}_n^\times$. $\square$

In the remark after Proposition 7.6 we observed that $F(\mu_{(m,n)}) \subset F(\mu_m) \cap F(\mu_n)$ and then gave an example to show that equality is generally not the case. However, using the theorem we have just proved, we may show that, in the case where the field $F$ is $\mathbb{Q}$, then we do indeed have equality.

**Corollary 7.5** The property

$$\mathbb{Q}(\mu_{(m,n)}) = \mathbb{Q}(\mu_m) \cap \mathbb{Q}(\mu_n)$$

is true for all $m, n \in \mathbb{N}^\times$.

**Proof** As $\mathbb{Q}(\mu_{(m,n)}) \subset \mathbb{Q}(\mu_m) \cap \mathbb{Q}(\mu_n)$, we only need to prove that

$$[\mathbb{Q}(\mu_{(m,n)}) : \mathbb{Q}] = [\mathbb{Q}(\mu_m) \cap \mathbb{Q}(\mu_n) : \mathbb{Q}].$$

From Proposition 7.6 we know that $\mathbb{Q}(\mu_m)\mathbb{Q}(\mu_n) = \mathbb{Q}(\mu_{[m,n]})$. Now, using Corollary 6.1, we obtain

$$[\mathbb{Q}(\mu_{[m,n]}) : \mathbb{Q}] = \frac{[\mathbb{Q}(\mu_m) : \mathbb{Q}][\mathbb{Q}(\mu_n) : \mathbb{Q}]}{[\mathbb{Q}(\mu_m) \cap \mathbb{Q}(\mu_n) : \mathbb{Q}]}.$$

Now, using the theorem, we have

$$\phi([m,n]) = \frac{\phi(m)\phi(n)}{[\mathbb{Q}(\mu_m) \cap \mathbb{Q}(\mu_n) : \mathbb{Q}]}.$$

However,

$$\phi([m,n])\phi(m,n) = \phi(m)\phi(n) \implies [\mathbb{Q}(\mu_m) \cap \mathbb{Q}(\mu_n) : \mathbb{Q}] = \phi((m,n)) = [\mathbb{Q}(\mu_{(m,n)}) : \mathbb{Q}].$$

This finishes the proof. $\square$

There are other interesting questions concerning cyclotomic extensions of the rational numbers. We will now consider two of these, namely the number of roots of unity in a cyclotomic extension and the coincidence of two such extensions. We will begin with two results concerning Euler’s totient function $\phi$.

**Proposition 7.8** For any given positive integer $N$, there are at most finitely many integers $n$ such that $\phi(n) = N$. 
PROOF Let $N$ be a positive integer and $p$ the least prime number greater than $N + 1$. Suppose that $n$ is an integer such that $\phi(n) = N$. If $q \geq p$ is a prime divisor of $n$, then $n = q^k m$, for some $k, m \in \mathbb{N}^*$, with $(q, m) = 1$. We have

$$\phi(n) = \phi(q^k)\phi(m) \geq q - 1 \geq p - 1 > N,$$

a contradiction. Therefore no prime divisor of $n$ is greater than $N + 1$. In particular, the distinct prime divisors of $n$ belong to a finite set. Let us note these primes $p_1, \ldots, p_s$. Then

$$n = p_1^{a_1} \cdots p_s^{a_s} \implies \phi(n) = \prod_{i=1}^{s} p_i^{a_i - 1}(p_i - 1).$$

For each prime $p_i$ we have

$$\phi(n) \geq p_i^{a_i - 1}(p_i - 1).$$

If $a_i$ sufficiently large, the expression on the right hand side of the equality is greater than $N$, hence there is a finite number of choices for the exponents. Therefore the set of all $n$ such that $\phi(n) = N$ is finite. \qed

**Remark** If $N$ is not 1 or an even number, then there are no integers $n$ such that $\phi(n) = N$. It has been shown that, for any integer $k \geq 2$, there is an integer $N$ such that there are just $k$ solutions to the equation $\phi(n) = N$ [8]. For the case $k = 1$, the question is open.

**Corollary 7.6** We have

$$\lim_{n \to \infty} \phi(n) = \infty.$$

**PROOF** If $\lim_{n \to \infty} \phi(n) \neq \infty$, then there is an integer $N > 0$ and an infinite sequence of integers $(n_i)$ such that $\phi(n_i) \leq N$, for all $n_i$. For the values of the $\phi(n_i)$ let us write $N_1, \ldots, N_s$. There is a finite number of such values and $N_i \leq N$, for all $i$. However, from Proposition 7.8, there can only be a finite number of elements of the sequence whose image is equal to one of $N_i$. If we take an element $n_i$ larger than all these elements, then we must have $\phi(n_i) > \max N_j$, a contradiction. This implies that $\lim_{n \to \infty} \phi(n) = \infty$. \qed

We need another elementary result.

**Proposition 7.9** If $a$ and $b$ are positive integers, then

$$\phi(ab) = \frac{\phi(a)\phi(b)(a, b)}{\phi((a, b))}.$$

**PROOF** If $a = 1$ or $b = 1$, then the result is trivial, so suppose that this is not the case. Let $p_1, \ldots, p_s$ be the prime divisors of $a$ which are not divisors of $b$ and $q_1, \ldots, q_t$ the prime divisors of $b$ which are not divisors of $a$. Finally let $u_1, \ldots, u_r$ be the prime divisors of both $a$ and $b$. Then

$$\phi(ab) = \frac{ab \prod_{i=1}^{s} (1 - \frac{1}{p_i}) \prod_{j=1}^{r} (1 - \frac{1}{u_j}) \prod_{k=1}^{t} (1 - \frac{1}{q_k})}{\prod_{j=1}^{r} (1 - \frac{1}{u_j})} = \frac{\phi(a)\phi(b)(a, b)}{(a, b) \prod_{j=1}^{r} (1 - \frac{1}{u_j})} = \frac{\phi(a)\phi(b)(a, b)}{\phi((a, b))}.$$
This ends the proof. □

We may now handle the questions referred to before Proposition 7.8. We will say that a root of unity is an $n$th root of unity for some $n \in \mathbb{N}^*$. By definition, the set $\mathbb{Q}(\mu_m)$ contains the $m$th roots of unity in $\mathbb{C}$. There are $m$ such roots of unity. The following result shows that if, if $m$ is even, then $\mathbb{Q}(\mu_m)$ contains no other roots of unity and, if $m$ is odd, then $\mathbb{Q}(\mu_m)$ contains the $m$th roots of unity and $m$ other roots of unity.

**Theorem 7.8**  If $m$ is a positive integer, then the number of roots of unity in $\mathbb{Q}(\mu_m)$ is $[2, m]$.

**Proof** In this proof $\zeta$ denotes a primitive $m$th root of unity; then $-\zeta \in \mathbb{Q}(\mu_m)$ and, by Theorem 7.5, it has order $2m$, if $m$ is odd. This implies that the set $\mu_{[2,m]} \subset \mathbb{Q}(\mu_m)$. We have shown that $\mathbb{Q}(\mu_m)$ contains $\mu_{[2,m]}$. Let us show that $\mathbb{Q}(\mu_m)$ contains no other roots of unity.

We claim that there is a largest $r$, which we note $\bar{r}$, for which $\mathbb{Q}(\mu_m)$ contains a primitive $r$th root of unity. If $\mathbb{Q}(\mu_m)$ contains a primitive $r$th root of unity, then $\mu_r \subset \mathbb{Q}(\mu_m)$, which implies that $\mathbb{Q}(\mu_r) \subset \mathbb{Q}(\mu_m)$ and

$$[\mathbb{Q}(\mu_m) : \mathbb{Q}] = [\mathbb{Q}(\mu_m) : \mathbb{Q}(\mu_r)] [\mathbb{Q}(\mu_r) : \mathbb{Q}] \implies \phi(m) \geq \phi(r).$$

Now, using Corollary 7.6, we see that there is a largest $r$ for which $\mathbb{Q}(\mu_m)$ contains a primitive $r$th root of unity.

Suppose now that $x$ is an $m$th root of unity belonging to $\mathbb{Q}(\mu_m)$ and $\bar{r}$ a primitive $r$th root of unity. From Corollary 7.3, there is a power $a$ of $x$ such that $\sigma(x^a y) = [m, \bar{r}]$. Since $x^a y \in \mathbb{Q}(\mu_m)$, the definition of $\bar{r}$ implies that $[n, \bar{r}] \leq \bar{r}$. It follows that $[n, \bar{r}] = \bar{r}$ and $n|\bar{r}$. Finally, every root of unity belongs to $\mu_r$.

Let us now show that $\bar{r} = [2, m]$. As $\zeta$ is an $m$th root of unity, from what we have just seen, $m$ divides $\bar{r}$. Let $\bar{r} = ms$. Using Proposition 7.9, we have

$$\phi(\bar{r}) = \phi(m) = \frac{\phi(m) \phi(s)(m, s)}{\phi((m, s))} \geq \phi(m) \phi(s).$$

Now, as $m|\bar{r}$, we must have $\mathbb{Q}(\mu_m) \subset \mathbb{Q}(\mu_r)$. Given that $\mathbb{Q}(\mu_m)$ contains a primitive $r$th root of unity, we also have $\mathbb{Q}(\mu_r) \subset \mathbb{Q}(\mu_m)$ and so $\mathbb{Q}(\mu_m) = \mathbb{Q}(\mu_r)$. This implies that

$$\phi(m) = \phi(\bar{r}) \implies 1 \geq \phi(s) \implies \phi(s) = 1 \implies s = 1 \text{ or } s = 2,$$

and so $\bar{r} = m$ or $\bar{r} = 2m$. If $m$ is even, then $\phi(2m) = 2\phi(m) > \phi(m)$, so $\bar{r} = m$; on the other hand, if $m$ is odd, then $-\zeta$ has order $2m$, so $\bar{r} \geq 2m$, and so $\bar{r} = 2m$. We have shown that $\bar{r} = [2, m]$.

To conclude, we have shown that the set of roots of unity belonging to $\mathbb{Q}(\mu_m)$ contains $\mu_{[2,m]}$ and is contained in $\mu_{[2,m]}$. This implies that this set is $\mu_{[2,m]}$. □

**Corollary 7.7**  If $m \neq n$, then $\mathbb{Q}(\mu_m) = \mathbb{Q}(\mu_n)$ if and only if $n$ is odd and $m = 2n$, or $m$ is odd and $n = 2m$.

**Proof** If $m$ is even, then $\mathbb{Q}(\mu_m)$ has $m$ roots of unity. If $\mathbb{Q}(\mu_m) = \mathbb{Q}(\mu_n)$, then $\mathbb{Q}(\mu_n)$ also has $m$ roots of unity. If $n$ is even, then $\mathbb{Q}(\mu_n)$ has $n$ roots of unity, so $m = n$, a contradiction. It follows that $n$ is odd and $\mathbb{Q}(\mu_n)$ has $2n$ roots of unity. Thus we have $m = 2n$.

If $m$ is odd, then $\mathbb{Q}(\mu_m)$ has $2m$ roots of unity. If $\mathbb{Q}(\mu_m) = \mathbb{Q}(\mu_n)$, then $\mathbb{Q}(\mu_n)$ also has $2m$ roots of unity. If $n$ is odd, then $\mathbb{Q}(\mu_n)$ has $2n$ roots of unity, so $m = n$, a contradiction. It follows that $n$ is even and has $n$ roots of unity. Thus we have $2m = n$. □
7.5 Cyclotomic extensions of finite fields

We have looked in some detail at cyclotomic extensions of \( \mathbb{Q} \). We will now consider cyclotomic extensions of finite fields. Being finite extensions of finite fields such extensions are Galois extensions (Proposition 3.1, Corollary 5.1). We will begin with a preliminary result, which is interesting in its own right. We recall that the cardinal of a finite field has the form \( p^k \), where \( p \) is a prime number and \( k \) a positive integer.

**Theorem 7.9** Let \( F \) be a finite field, with \( |F| = p^k \), and \( E \) a finite extension of \( F \) of degree \( n \). Then the Galois group \( G = \text{Gal}(E/F) \) is cyclic and generated by the Frobenius automorphism \( Fr : x \mapsto x^{p^k} \).

**Proof** To simplify the notation, let us write \( q \) for \( p^k \). First we show that the mapping \( Fr \) is indeed an automorphism. \( Fr \) is clearly linear. If \( x^q = 0 \), then \( x = 0 \), because \( x^q = x \), for all \( x \in F \), so \( Fr \) is injective. An endomorphism of a finite-dimensional vector space is also surjective, so \( Fr \) is a bijective endomorphism of \( E \). Finally, \( (xy)^q = x^q y^q \), so \( Fr \) is an automorphism of \( E \). As \( x^q = x \), for all \( x \in F \), \( Fr \in G \).

If \( x \in E \), then \( x^q = x \), which implies that \( o(Fr) \leq n \). However, if \( \bar{x} \) is a generator of \( E^* \), then \( \bar{x}^s \neq \bar{x} \), for any \( s < q^n \), and so \( o(Fr) = n \). Now, \( |G| = [E : F] = n \), therefore \( G \) is cyclic with generator \( Fr \).

Now we turn to cyclotomic extensions of \( \mathbb{F}_p \). (As usual we suppose that \( p \) and \( n \) are coprime.) From the previous theorem the Galois group of a cyclotomic extension \( \mathbb{F}_p(\mu_n) / \mathbb{F}_p \) must be cyclic. We are interested in finding a generator of this group in \( \mathbb{Z}_n^* \). As the Frobenius mapping \( Fr \) defined on \( E \) maps every element \( x \) of \( \mathbb{F}_p(\mu_n) \) to \( x^p \), we have \( \phi(Fr) = [p] \), where \( \phi \) is the mapping defined in Theorem 7.4. Hence we have

**Proposition 7.10** The image of the Galois group \( G = \text{Gal}(\mathbb{F}_p(\mu_n) / \mathbb{F}_p) \) in \( \mathbb{Z}_n^* \) under the mapping \( \phi \) is generated by the congruence class \( [p] \), so the cardinal of \( G \) is the order of \( [p] \) in \( \mathbb{Z}_n^* \).

**Exercise 7.6** Find the value of the following degrees:

\[
[F_3(\mu_7) : F_3] \quad [F_5(\mu_4) : F_5] \quad [F_7(\mu_{10}) : F_7].
\]

7.6 Quadratic and cyclotomic extensions

An easy calculation shows that

\[
(e^{\frac{2\pi i}{5}} - e^{\frac{4\pi i}{5}} - e^{\frac{6\pi i}{5}} + e^{\frac{8\pi i}{5}})^2 = 5,
\]

which implies that the expression between the brackets is a square root of 5. As this expression is an element of the cyclotomic field \( \mathbb{Q}(\mu_5) \) the quadratic extension \( \mathbb{Q}(\sqrt{5}) \) of the rationals is contained in the cyclotomic field \( \mathbb{Q}(\mu_5) \). The goal of this section is to generalize this by showing that any quadratic extension of the rationals is included in some cyclotomic field. In fact, we may say more. A quadratic extension \( E \) of \( \mathbb{Q} \) is abelian, i.e., the Galois group \( \text{Gal}(E/\mathbb{Q}) \) is abelian, since its cardinal is 2 (see Theorems 3.5, 5.1 and 6.1). The Kronecker-Weber Theorem, which we will prove further on, states that any finite abelian extension of \( \mathbb{Q} \) is included in some cyclotomic field.
We begin with Gauss sums. Let \( \zeta \) be a primitive \( p \)-th root of unity, where \( p \) is an odd prime number. We define the Gauss sum by

\[
\tau_p = \sum_{k=1}^{p-1} \left( \frac{k}{p} \right) \zeta^k,
\]

where \( \left( \frac{\cdot}{p} \right) \) denotes the Legendre symbol. Then

**Proposition 7.11** We have

\[
\tau_p^2 = (-1)^{\frac{p+1}{2}} p.
\]

**Proof** First

\[
\tau_p^2 = \sum_{k,l=1}^{p-1} \left( \frac{k}{p} \right) \left( \frac{l}{p} \right) \zeta^{k+l}.
\]

If we fix \( k \in \{1, \ldots, p-1\} \), then the set \( \{k \cdot 1, k \cdot 2, \ldots, k \cdot (p-1)\} \) is a set of representatives of the nonzero congruence classes of \( \mathbb{Z}_p \), hence we can write

\[
\tau_p^2 = \sum_{k=1}^{p-1} \left( \sum_{m=1}^{p-1} \zeta^{k(1+m)} \right) \left( \frac{m}{p} \right).
\]

If \( m \neq p-1 \), then the sequence \( \zeta^{1+m}, \zeta^{2(1+m)}, \ldots, \zeta^{(p-1)(1+m)} \) runs through all the \( p \)-th roots of unity with the exception of 1, hence their sum has the value \(-1\). On the other hand, if \( m = p-1 \), then the sum of the members of the sequence has the value \( p-1 \). Therefore

\[
\tau_p^2 = -\sum_{m=1}^{p-2} \left( \frac{m}{p} \right) + (p-1) \left( \frac{p-1}{p} \right) = -\sum_{m=1}^{p-2} \left( \frac{m}{p} \right) + p \left( \frac{-1}{p} \right) = p \left( \frac{-1}{p} \right),
\]

because the number of nonzero squares in \( \mathbb{Z}_p \) is the same as that of the nonsquares. The result follows from the fact that \( \left( \frac{-1}{p} \right) = (-1)^{\frac{p-1}{2}} \).

**Corollary 7.8** We have

\[
\sqrt{(-1)^{\frac{p-1}{2}} p} \in \mathbb{Q}(\mu_p).
\]

**Proof** \( \tau_p \) is a square root of \( \frac{\tau_p^2}{\tau_p} = (-1)^{\frac{p-1}{2}} p \) and \( \tau_p \in \mathbb{Q}(\zeta) = \mathbb{Q}(\mu_p) \).

We now consider the relation between quadratic and cyclotomic extensions of \( \mathbb{Q} \).
Proposition 7.12 Let $p$ be an odd prime number. Then the field $\mathbb{Q}(\mu_p)$ contains a unique quadratic extension of $\mathbb{Q}$, namely

$$\mathbb{Q}\left(\sqrt{(-1)^{\frac{p-1}{2}}p}\right).$$

(If $p \equiv 1(\text{mod } 4)$, then $(-1)^{\frac{p-1}{2}}p = p$ and if $p \equiv 3(\text{mod } 4)$, then $(-1)^{\frac{p-1}{2}}p = -p$.)

Proof Theorem 7.7 ensures that $G = \text{Gal}(\mathbb{Q}(\mu_p)/\mathbb{Q})$ is cyclic of order $p - 1$, hence contains a unique subgroup $H$ of order $\frac{p-1}{2}$. Let $K$ be a field intermediate between $\mathbb{Q}$ and $\mathbb{Q}(\mu_p)$ such that $[K: \mathbb{Q}] = 2$. By Theorem 5.1, $\mathbb{Q}(\mu_p)$ is a Galois extension of $\mathbb{Q}$. Consequently, Proposition 5.3 ensures that $\mathbb{Q}(\mu_p)$ is a Galois extension of $K$. Thus, Theorem 6.1 entails that $\text{Gal}(\mathbb{Q}(\mu_p)/K)$ is a subgroup of $G$ of order $\frac{p-1}{2}$. From the unicity of $H$, we have $H = \text{Gal}(\mathbb{Q}(\mu_p)/K)$. Theorem 6.4 now implies that $K = \mathcal{F}(H)$. We have shown that $\mathbb{Q}(\mu_p)$ contains a unique quadratic extension.

To conclude the proof it suffices to notice that $\mathbb{Q}\left(\sqrt{(-1)^{\frac{p-1}{2}}p}\right)$ is a quadratic extension of $\mathbb{Q}$ contained in $\mathbb{Q}(\mu_p)$, by Corollary 7.8. \qed

For the moment we have only seen that quadratic extensions of a certain form are included in a cyclotomic extension of $\mathbb{Q}$. This is not difficult to extend. First let us suppose that $p \equiv 1(\text{mod } 4)$ and consider $-p$. We may write $\sqrt{-p} = i\sqrt{p}$. Then, using Proposition 7.6, we obtain

$$\mathbb{Q}(\sqrt{-p}) = \mathbb{Q}(i\sqrt{p}) \subset \mathbb{Q}(i\mathbb{Q}(\sqrt{p}) \subset \mathbb{Q}(\mu_4) \mathbb{Q}(\mu_p) = \mathbb{Q}(\mu_{4p}).$$

If $p \equiv 3(\text{mod } 4)$, then

$$\mathbb{Q}(\sqrt{p}) = \mathbb{Q}(i\sqrt{-p}) \subset \mathbb{Q}(i) \mathbb{Q}(\mu_p) = \mathbb{Q}(\mu_{4p}).$$

We have considered odd primes. What can we say about the prime 2? We claim that $\mathbb{Q}(\sqrt{2})$ and $\mathbb{Q}(\sqrt{-2})$ are included in $\mathbb{Q}(\mu_8)$. First we notice that $\zeta = e^{i\pi/4}$ is a primitive 8th root of unity. Also, $\zeta^2 = \zeta^{-1}$. Hence, $\zeta + \zeta^{-1}$ is an element of $\mathbb{Q}(\mu_8)$. However, this sum has the value $\sqrt{2}$. It follows that $\mathbb{Q}(\sqrt{2}) \subset \mathbb{Q}(\mu_8)$.

Now, $\sqrt{-2} = i\sqrt{2}$ and $i, \sqrt{2} \in \mathbb{Q}(\mu_8)$, therefore $\sqrt{-2} \in \mathbb{Q}(\mu_8)$ and it follows that $\mathbb{Q}(\sqrt{-2}) \subset \mathbb{Q}(\mu_8)$.

Theorem 7.10 Every quadratic extension of the rationals is included in some cyclotomic extension.

Proof We have seen that, if $E$ is a quadratic extension of the rationals, then there is a squarefree integer $d$ such that $E = \mathbb{Q}(\sqrt{d})$ (Theorem 3.5). If $d = \pm p_1 \cdots p_k$, where the $p_i$ are distinct primes, then

$$\mathbb{Q}(\sqrt{d}) = \mathbb{Q}(\sqrt{p_1} \sqrt{p_2} \cdots \sqrt{p_k}) \subset \mathbb{Q}(\sqrt{\pm p_1}) \mathbb{Q}(\sqrt{\pm p_2}) \cdots \mathbb{Q}(\sqrt{\pm p_k}).$$

However, we have just seen that, if $p$ is a prime number, there is an integer $n \geq 2$ such that $\mathbb{Q}(\sqrt{p}) \subset \mathbb{Q}(\mu_n)$ and the same applies for $-p$. Hence, there are integers $n_i \geq 2$ such that

$$\mathbb{Q}(\sqrt{d}) \subset \mathbb{Q}(\mu_n_1) \mathbb{Q}(\mu_n_2) \cdots \mathbb{Q}(\mu_n_k) = \mathbb{Q}(\mu_{n_1 n_2 \cdots n_k}).$$

This ends the proof. \qed

Exercise 7.7 Find a condition on $d$ which ensures that $\mathbb{Q}(\sqrt{d}) \subset \mathbb{Q}(\mu_d)$.  68
Remark We have seen that the square root of an integer lies in some cyclotomic extension of $\mathbb{Q}$. A natural question arises, namely, if $p$ is an odd prime, does a $p$th root of an integer necessarily lie in some cyclotomic extension of $\mathbb{Q}$. In fact, this is not in general true. Let $\alpha = \sqrt[p]{2}$, where $p$ is an odd prime and $\zeta$ a primitive $n$th root of unity for some $n$. The Galois group $G = \text{Gal}(\mathbb{Q}(\zeta)/\mathbb{Q})$ is abelian. If $\alpha \in \mathbb{Q}(\zeta)$, then $\mathbb{Q}(\alpha)$ is a subfield of $\mathbb{Q}(\zeta)$ and the Galois group $G' = \text{Gal}(\mathbb{Q}(\zeta)/\mathbb{Q}(\alpha))$ is normal in $G$, because $G'$ is a subgroup of the abelian group $G$. This implies that $\mathbb{Q}(\alpha)$ is a normal extension of $\mathbb{Q}$. However, this is not so, because lies in $\mathbb{Q}(\alpha)$, but the other roots of $f(X) = -2 + X^p$ do not. It follows that $\alpha \notin \mathbb{Q}(\zeta)$.

7.7 Orbits of the Galois group action

In Section 7.1 we introduced the action of a Galois group of a separable polynomial $f$ on its roots. In this section we aim to look more closely at this. In particular, we will show that there is an interesting relation between the orbits of the action and the decomposition into irreducible polynomials of the polynomial $f$. We consider a separable polynomial $f \in F[X]$, with set of roots $A = \{\alpha_1, \ldots, \alpha_n\}$ in a splitting field $E$ and we note $\Phi$ the action of the Galois group $G = \text{Gal}(E/F)$ on $A$. We write $O_1, \ldots, O_r$ for the orbits of $\Phi$ and set $n_i = |O_i|$.

Proposition 7.13 Let $S$ be a subset of $A$ and the polynomial $f_S \in E[X]$ be defined by

$$f_S(X) = \prod_{\alpha_i \in S} (-\alpha_i + X).$$

If $S^G$ is the subset of $S$ fixed by $G$, i.e., the subset of elements $x \in A$ for which $\sigma(x) = x$ for all $\sigma \in G$, then $f_S \in F[X]$ if and only if $S^G = S$.

Proof Suppose that $f_S \in F[X]$ and take $\sigma \in G$. Let

$$\tilde{f}_S(X) = \prod_{\alpha_i \in S} (-\sigma(\alpha_i) + X).$$

The coefficients $b_k$ of this polynomial are expressions, i.e., sums of products, of the $\sigma(\alpha_i)$. As $\sigma$ is an automorphism, a coefficient $b_k$ is the image under $\sigma$ of the corresponding sum of products of the $\alpha_i$, i.e., $b_k = \sigma(a_k)$. As $\sigma$ fixes the elements of $F$, $a_k = b_k$, for all $k$ and so $\tilde{f}_S = f_S$. This implies that $\sigma$ fixes $S$. As this is so for all $\sigma \in G$, we have $S^G = S$.

Now suppose that $S^G = S$ and let $\sigma$ be an element of $G$. As $\sigma$ fixes $S$, $\tilde{f}_S = f_S$. However, this is so for all $\sigma \in G$, so the coefficients of $f_S$ belong to the set of elements of $E$ fixed by $G$, i.e., the field $F$ (see Theorem 6.2). Hence $f_S \in F[X]$.

Remark Let $g$ be a monic, irreducible factor of the polynomial $f$. Then there is a subset $S$ of $A$ such that $g = f_S$. As $g \in F[X]$, by the previous proposition, we have $S^G = S$, which implies that $S$ is a union of orbits of the action $\Phi$.

Proposition 7.14 Suppose that the polynomial $f_S$ defined above is in $F[X]$. Then $f_S$ is irreducible if and only if $S$ is a minimal set fixed by $G$.

Proof Suppose that $f_S$ is irreducible. If $S'$ is strictly included in $S$ and $S'$ is fixed by $G$, then $f_{S'} \in F[X]$ and $f_{S'} | f$, with $\deg f_{S'} < \deg f_S$. This is a contradiction to the irreducibility of $f_S$. Hence $S$ must be minimal.

Now suppose that $S$ is a minimal set fixed by $G$. If $f_S$ is not irreducible, then there exists $g \in F[X]$ which is monic, divides $f_S$ and so that $\deg g < \deg f_S$. There exists $S'$ strictly
included in $S$ such that $g = f_S$, and so $S$ is not minimal, a contradiction. It follows that $f_S$ is irreducible.

We may now prove the main result of this section.

**Theorem 7.11** If the separable polynomial $f \in F[X]$ has the decomposition into irreducible factors

$$f = \lambda f_1 \cdots f_r,$$

where $\lambda \in F$ and the $f_i$ are monic, then the action $\Phi$ has $r$ orbits $O_1, \ldots, O_r$, with $\deg f_i = |O_i|$.

**Proof** The minimal sets fixed by $G$ are the orbits of $\Phi$, therefore the monic irreducible factors of $f$ are in one-to-one correspondence with the orbits and we have

$$f = \lambda f_{O_1} \cdots f_{O_r},$$

where $\lambda \in F$ and the polynomials $f_{O_i}$ are monic, irreducible. The degree of $f_{O_i}$ is $n_i = |O_i|$.

It is interesting to consider the case where $F = F_p$. From Theorem 7.4 we know that, if $E$ is a finite Galois extension of $F_p$, then the Galois group $G = Gal(E/F_p)$ is cyclic and generated by the Frobenius automorphism $Fr : x \mapsto x^p$. If we suppose that $E$ is a splitting field of a separable polynomial $f \in F_p[X]$, then the orbits of the action $\Phi$ defined above are of the form $O_i = \{Fr^s(\alpha_j)\}_{s \in \mathbb{N}}$, for some $\alpha_j$. If $s'$ is the smallest index $s \geq 1$ such that $Fr^s(\alpha_j) = \alpha_j$, then $s' = n_i - 1$ and $O_i = \{\alpha_j, Fr(\alpha_j), \ldots, Fr^{n_i-1}(\alpha_j)\}$, i.e., $O_i$ is a cycle of $Fr$ of length $n_i = \deg f_i$. 70
Chapter 8

Dedekind’s reduction theorem

We recall that, if \( f \) is a polynomial in \( \mathbb{Z}[X] \) and \( p \) a prime number, then we may define \( \bar{f} \in \mathbb{F}_p[X] \) by replacing the coefficients of \( f \) by their congruence classes modulo \( p \). The polynomial \( \bar{f} \) so obtained is called the \textit{reduction modulo} \( p \) of \( f \). We will sometimes refer to \( f \) as a reduced polynomial. In this chapter we aim to establish an important relation between the Galois groups of \( f \) over \( \mathbb{Q} \) and \( \bar{f} \) over \( \mathbb{F}_p \), which will enable us to find useful information about the former Galois group. We will need some preliminaries.

8.1 A basic result in module theory

We say that a module \( M \) over a ring \( R \) is \textit{finitely generated} if there are \( m_1, \ldots, m_s \in M \) such that every element \( m \in M \) can be expressed in at least one way as

\[ m = r_1m_1 + \cdots + r_sm_s, \]

with the \( r_i \in R \). The module \( M \) is \textit{free} if it has a \textit{basis}, i.e., a set \( U \) which has the properties:

- \( U \) is a generating set: every element \( m \in M \) can be expressed as
  \[ m = r_1u_1 + \cdots + r_su_s, \]
  with the \( u_i \in U \) and the \( r_i \in R \);
- \( U \) is an independent set:
  \[ r_1u_1 + \cdots + r_su_s = 0 \implies r_i = 0, \quad \text{for all } i. \]

Let \( M \) be a module over an integral domain \( R \). If \( x \in M \) and there exists \( r \in R^* \) such that \( rx = 0 \), then we say that \( x \) is a \textit{torsion element}. The set of torsion elements form a submodule of \( M \), which we write \( tM \). (Clearly \( tM \) is closed under scalar multiplication; if \( rx = 0 \) and \( sx = 0 \), then \( rs(x+y) = 0 \), so \( tM \) is closed under addition.) We say that \( M \) is \textit{torsion-free} if \( tM = \{0\} \) and \textit{torsion} if \( tM = M \). We now bring these ideas together.

**Proposition 8.1** Let \( R \) be principal ideal domain and \( M \) a finitely generated \( R \)-module. Then \( M \) has a finite basis if and only if \( M \) is torsion-free.

We will give a proof of this result in Appendix E.

**Exercise 8.1** Show that a free module over an integral domain is torsion-free.
8.2 Dedekind’s lemma

In this section we present an important result due to Dedekind, which we will need further on in this chapter. Let $G$ be a (multiplicative) semi-group and $F$ a field. A character of $G$ into $F$ is a mapping from $G$ into $F$ which preserves multiplication and is not identically zero. We will write $\text{Char}(G, F)$ for the set of characters from $G$ into $F$. The set of all mappings from $G$ into $F$, which we note $F^G$, can be given a vector space structure over $F$ with the vector space operations defined pointwise. The following result is referred to as Dedekind’s lemma.

**Theorem 8.1** The set of characters $\text{Char}(G, F)$ is a linearly independant subset of $F^G$.

**Proof** Let $n \geq 1$ and $\chi_1, \ldots, \chi_n$ be distinct elements of $\text{Char}(G, F)$. Suppose that

$$a_1\chi_1 + \cdots + a_n\chi_n = 0, \quad (8.1)$$

where $a_1, \ldots, a_n \in F$. We will show by induction that $a_1 = \cdots = a_n = 0$.

For $n = 1$, let $x \in G$ be such that $\chi_1(x) \neq 0$. Then $a_1\chi_1(x) = 0$ implies that $a_1 = 0$. Now suppose that $n > 1$ and that the result is true up to $n - 1$. Since $\chi_1 \neq \chi_n$, there exists $y \in G$ such that $\chi_1(y) \neq \chi_n(y)$. Evaluating equation (8.1) at $x$ and $yx$, where $x$ is an arbitrary member of $G$, we obtain

$$a_1\chi_1(x) + \cdots + a_n\chi_n(x) = 0 \quad (8.2)$$

and

$$a_1\chi_1(y)\chi_1(x) + \cdots + a_n\chi_n(y)\chi_n(x) = 0. \quad (8.3)$$

We now multiply equality (8.2) by $\chi_n(y)$ and subtract it from equality (8.3). Bearing in mind that the element $x$ was chosen arbitrarily, we obtain

$$a_1(\chi_1(y) - \chi_n(y))\chi_1 + \cdots + a_{n-1}(\chi_{n-1}(y) - \chi_n(y))\chi_{n-1} = 0.$$ 

From the induction hypothesis we deduce that all the coefficients of the linear combination on the left hand side of the equality have the value 0. In particular, $a_1(\chi_1(y) - \chi_n(y)) = 0$. As $\chi_1(y) - \chi_n(y) \neq 0$, we must have $a_1 = 0$. However, now equation (8.1) is reduced to $n - 1$ terms and so, using the induction hypothesis again, we obtain $a_2 = \cdots = a_n = 0$. \hfill \square

**Remark** A character is not required to have only nonzero values; it is sufficient that it has at least one nonzero value. However, if $G$ is a monoid, then the image of an invertible element is nonzero. In particular, if $G$ is a group, then the image of $G$ under a character is a subgroup of the multiplicative subgroup $F^*$ of $F$.

**Corollary 8.1** A set of distinct automorphisms $S = \{\sigma_1, \ldots, \sigma_n\}$ on a field $F$ is independant.

**Proof** An automorphism $\sigma$ of a field $F$, when restricted to the multiplicative group $F^*$ becomes a group automorphism, hence $\sigma$ is a character of the group $F^*$ into the field $F$. \hfill \square

8.3 Splitting fields of polynomials in $\mathbb{Z}[X]$

In this section (and the following sections) we aim to consider certain properties of splitting fields of monic polynomials belonging to $\mathbb{Z}[X]$. Let $f \in \mathbb{Z}[X]$ be monic, $A = \{a_1, \ldots, a_n\}$ the set of roots of $f$ in $\mathbb{C}$ and $E$ a splitting field of $f$ contained in $\mathbb{C}$. We may consider $f$ as a polynomial in $\mathbb{Q}[X]$. Then, from Proposition 2.2, we have

$$E = \mathbb{Q}[a_1, \ldots, a_n],$$

72
i.e., \( E \) is composed of the polynomials in the \( \alpha_i \) with coefficients in \( \mathbb{Q} \). We set
\[
D = \mathbb{Z}[\alpha_1, \ldots, \alpha_n].
\]
Then \( D \) is a subring of \( E \) and also a \( \mathbb{Z} \)-module.

**Proposition 8.2** The \( \mathbb{Z} \)-module \( D \) is finitely generated and torsion-free, therefore has a finite basis \( U = (u_1, \ldots, u_r) \).

**Proof** If \( f(X) = \sum_{i=0}^{n} a_i X^i \) and \( \alpha \in A \), then \( \alpha^n = -\sum_{i=0}^{n-1} a_i \alpha^i \), therefore \( D \) is generated by the elements \( \alpha_1^e_1 \alpha_2^e_2 \cdots \alpha_n^e_n \), with \( 0 \leq e_i \leq n - 1 \). Thus \( D \) is finitely generated.

If \( am = 0 \), with \( a \neq 0 \), then considering \( D \subseteq E \), we have
\[
-a^{-1}(am) = (a^{-1}a)m = 0 \implies m = 0.
\]
Thus \( D \) is torsion-free.

As \( \mathbb{Z} \) is a P.I.D. and \( D \) is finitely generated and torsion-free, we may apply Proposition 8.1 to obtain the existence of a finite basis \( U = (u_1, \ldots, u_r) \).

A natural question now arises: Can we find a natural basis of the \( \mathbb{Q} \)-vector space \( E \)? In fact, this is the case.

**Proposition 8.3** The basis \( U = (u_1, \ldots, u_r) \) of \( D \) is a basis of the \( \mathbb{Q} \)-vector space \( E = \mathbb{Q}[\alpha_1, \ldots, \alpha_n] \).

**Proof** \( E \) is the fraction field of \( D \), so, by Corollary E.1, \( U \) is a basis of the \( \mathbb{Q} \)-vector space \( E \). \( \square \)

### 8.4 Splitting fields of reduced polynomials

Our aim in this section is to find a splitting field of a reduced polynomial.

**Proposition 8.4** Let \( p \) be a prime number and \( M \) a maximal ideal of \( D \) which contains the proper ideal \( Dp \). If \( f \in \mathbb{Z}[X] \) and is monic, then \( K = D/M \) is a splitting field of \( f \), the reduction modulo \( p \) of \( f \).

**Proof** It is clear that the characteristic of \( K \) is \( p \), hence \( K \) is an extension of \( \mathbb{F}_p \). Let us write \( \pi \) for the standard projection of \( D \) on \( K \). If \( U = (u_i) \) is the basis found in the preceding section and
\[
x = a_1 u_1 + \cdots + a_r u_r, \quad \text{with} \quad a_i \in \mathbb{Z},
\]
then
\[
\pi(x) = \pi(a_1) \pi(u_1) + \cdots + \pi(a_r) \pi(u_r).
\]
We may identify the image of \( \pi \) restricted to \( \mathbb{Z} \) with \( \mathbb{F}_p \), because the kernel of this mapping is \( \mathbb{Z} \cap M = \mathbb{Z}p \). Thus we may consider the \( \pi(a_i) \) belonging to \( \mathbb{F}_p \). Therefore \( \{ \pi(u_i) \} \) is a generating set of \( K \) over \( \mathbb{F}_p \) and \( K \) is a finite extension of \( \mathbb{F}_p \). We next notice that \( \bar{f} \) splits over \( K \):
\[
\bar{f}(X) = \tilde{\pi}(f(X)) = \tilde{\pi}(\prod_{i=1}^{n} (X - \alpha_i)) = \prod_{i=1}^{n} (\bar{x} - \pi(\alpha_i)),
\]
where \( \tilde{\pi} \) is the mapping of \( \mathbb{Z}[X] \) into \( \mathbb{F}_p[X] \) which corresponds to \( \pi \) and the \( \alpha_i \) are the roots of \( f \). In addition,
\[
K = \pi(D) = \pi(\mathbb{Z}[\alpha_1, \ldots, \alpha_n]) = \mathbb{F}_p[\pi(\alpha_1), \ldots, \pi(\alpha_n)] = \mathbb{F}_p(\pi(\alpha_1), \ldots, \pi(\alpha_n)),
\]
73
because $\mathbb{F}_p[\pi(\alpha_1), \ldots, \pi(\alpha_n)]$ is a field. It follows that $K$ is a splitting field of $\bar{f}$. □

The mapping $\pi : D \rightarrow K$ is a surjective ring homomorphism and the roots of $\bar{f}$ are the images of the roots of $f$. In fact, we may generalize this.

**Proposition 8.5** If $\phi : D \rightarrow K$ is a ring homomorphism, then $\phi$ restricted to $Z$ is the same for all $\phi \in \text{Hom}(D, K)$. Also, $\phi$ is surjective and the images of the roots of $f$ are roots of $\bar{f}$.

**Proof** That $\phi$ restricted to $Z$ is the same for all $\phi \in \text{Hom}(D, K)$ follows from the fact that $\phi(1) = 1 + M$.

Now we observe that $\tilde{\phi}(f(X)) = \tilde{\phi} \left( \prod_{i=1}^{n} (-\alpha_i + X) \right) = \prod_{i=1}^{n} (-\phi(\alpha_i) + X)$, hence the $\phi(\alpha_i)$ are the roots of $\bar{f}$.

Finally let us consider the surjectivity. We have $\phi(D) = \phi(Z[\alpha_1, \ldots, \alpha_n]) = \mathbb{F}_p[\phi(\alpha_1), \ldots, \phi_n(\alpha_n)]$.

Also, $\mathbb{F}_p[\phi(\alpha_1), \ldots, \phi(\alpha_n)]$ is a subset of $K$ and also a splitting field of $\bar{f}$ (Proposition 2.2), therefore $\mathbb{F}_p[\phi(\alpha_1), \ldots, \phi(\alpha_n)]$ is isomorphic to $K$. It follows that $\phi(D) = K$. □

**Remark** This generalization, which is interesting in its own right, will be used in a proof a little further on, namely that of Proposition 8.7.

### 8.5 Resultants and discriminants

In the following we will use the discriminant of a polynomial, which is useful in determining whether an extension is separable. However, in order to study this concept it is useful to introduce another concept, namely the resultant of two polynomials. There is an important relation between the discriminant of a polynomial and the resultant of a polynomial and its derivative. Here we will only introduce the subject. Further on we will handle it in more detail.

#### Resultants

We fix $m, n \in \mathbb{N}^*$. Let $F$ be a field, $f \in F_m[X]$, with coefficients $a_0, \ldots, a_m$ and $g \in F_n[X]$, with coefficients $b_0, \ldots, b_n$. We define the square $n + m$ **Sylvester matrix** $S_{m,n}(f, g)$ (or $S(f, g)$), if $m$ and $n$ are understood) as follows:

\[
S_{m,n}(f, g) = \begin{bmatrix}
  a_m & a_{m-1} & a_{m-2} & \ldots & 0 & 0 & 0 \\
  0 & a_m & a_{m-1} & \ldots & 0 & 0 & 0 \\
  \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots \\
  0 & 0 & 0 & \ldots & a_1 & a_0 & 0 \\
  0 & 0 & 0 & \ldots & a_2 & a_1 & a_0 \\
  b_n & b_{n-1} & b_{n-2} & \ldots & 0 & 0 & 0 \\
  0 & b_n & b_{n-1} & \ldots & 0 & 0 & 0 \\
  \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots \\
  0 & 0 & 0 & \ldots & b_1 & b_0 & 0 \\
  0 & 0 & 0 & \ldots & b_2 & b_1 & b_0 
\end{bmatrix}
\]
We obtain \( S_{m,n}(f,g) \) by shifting the line vector of the coefficients of \( f \) successively to the right by 0, 1, \ldots, \( n-1 \) steps and the vector line of the coefficients of \( g \) successively to the right by 0, 1, \ldots, \( m-1 \) steps and then filling in the remaining places with 0.

**Remark** If \( 0 \leq \deg f = k < m \), then we have \( a_m = a_{m-1} = \cdots = a_{k+1} = 0 \) and if \( f = 0 \), then \( a_i = 0 \), for all \( i \). We have an analogous situation if \( \deg g \neq n \).

Here is an example. With \( m = 3 \) an \( n = 2 \), we have

\[
S_{m,n}(f,g) = \begin{bmatrix}
a_3 & a_2 & a_1 & a_0 \\
0 & a_3 & a_2 & a_1 \\
b_2 & b_1 & b_0 & 0 \\
0 & 0 & b_2 & b_1 \\
0 & 0 & 0 & b_0 \\
\end{bmatrix}
\]

The resultant of \( f \) and \( g \), which we note \( R_{m,n}(f,g) \), (or \( R(f,g) \), if \( m \) and \( n \) are understood) is the determinant \( |S_{m,n}(f,g)| \). Clearly,

\[
R_{n,m}(g,f) = (-1)^{mn}R_{m,n}(f,g).
\]

**Remark** We may consider the \( a_i \) and \( b_j \) as variables. In this way we obtain a mapping from \( F^{m+1} \times F^{n+1} \) into \( F \), which is \( mn \)-homogeneous.

**Discriminants**

Let \( f(X) = \sum_{i=0}^m a_i X^i \) a polynomial with coefficients in a field \( F \). We suppose that the degree \( m \) of \( f \) is greater than 1 and that \( f \) has the roots \( \xi_1, \ldots, \xi_m \) in some splitting field \( E \). The **discriminant** of \( f \) is defined by

\[
\Delta(f) = a_m^{2m-2} \prod_{1 \leq i < j \leq m} (\xi_i - \xi_j)^2.
\]

From the theorem which follows this definition is unambiguous: it does not depend on the splitting field chosen.

It is useful to notice that \( \Delta(f) \) belongs to \( F \). Indeed, the multivariate polynomial

\[
A = a_m^{2m-2} \prod_{1 \leq i < j \leq m} (X_i - X_j)^2
\]

is a symmetric polynomial in \( F[X_1, \ldots, X_n] \). Consequently, from Corollary B.1, \( \Delta(f) \in F \). Using the same corollary, we may also say that, if \( f \in R[X] \), where \( R \) is an integral domain, then \( \Delta(f) \in R \).

The following result links the resultant and the discriminant.

**Theorem 8.2** If \( \text{char } F = 0 \) or \( \text{char } F = p > 0 \) and \( p \nmid m \), where \( \deg f = m \), then

\[
\Delta(f) = (-1)^{m(m-1)/2}a_m^{-1}R_{m,m-1}(f,f').
\]

**Remark** The polynomial \( f \) has a multiple root if and only if \( \Delta(f) = 0 \). From the above formula, we see that we are able to determine the existence of a multiple root only taking into account the coefficients of \( f \). We should also notice that the formulas show that the discriminant belongs to the field \( F \).
8.6 The Galois group of a polynomial and of its reduction

In this section we aim to show that the Galois group of the reduction of a monic polynomial \( f \in \mathbb{Z}[X] \) may be considered as a subgroup of the Galois group of \( f \). This will give us information about the Galois group of \( f \). We begin with a simple proposition, which we can prove using discriminants, thus justifying their introduction in the last section.

**Proposition 8.6** Let \( f \in \mathbb{Z}[X] \) be a monic polynomial, \( p \) a prime number and \( \bar{f} \in \mathbb{F}_p[X] \) the reduction modulo \( p \) of \( f \). Then, if \( \bar{f} \) is strongly separable, then so is \( f \).

**Proof** If \( M = (m_{ij}) \in M_n(\mathbb{Z}) \) and \( \bar{M} = (\bar{m}_{ij}) \in M_n(\mathbb{F}_p) \), where \( \bar{m}_{ij} \) is the congruence class of \( m_{ij} \) modulo \( p \), then \( \det \bar{M} = \det M \). Hence, if \( \deg f = n \), then

\[
R_{n,n-1}(f,f') = 0 \implies R_{n,n-1}(\bar{f},\bar{f}') = 0
\]

and it follows that, if \( \bar{f} \) is strongly separable, then so if \( f \). \( \square \)

We suppose from here on that \( \bar{f} \) is strongly separable and that \( E, D \) and \( K \) are defined as in Sections 7.3 and 7.4. We define a right action \( \Psi \) of \( G = Gal(E/\mathbb{Q}) \) on \( Hom(D,K) \), the set of ring homomorphisms of \( D \) into \( K \), by

\[
\Psi(\sigma, \phi) = \sigma.\phi = \phi \circ \sigma|_{D},
\]

for all \( \sigma \in G \) and \( \phi \in Hom(D,K) \). (The action is defined, because \( \sigma(D) \subset D \).)

**Proposition 8.7** The action \( \Psi \) is free and transitive.

**Proof** Let \( A \) be the set of roots of \( f \). If \( \phi \circ \sigma \) restricted to \( D \) is equal to \( \phi \), then \( (\phi \circ \sigma)|_A = \phi|_A \).

In addition, \( \sigma(A) \subset A \), so we may write

\[
\phi|_A = (\phi \circ \sigma)|_A = \phi|_A \circ \sigma|_A.
\]

From Proposition 8.5, \( \phi|_A \) is surjective from \( A \) into \( \bar{A} \), the set of roots of \( \bar{f} \). As \( \bar{f} \) is strongly separable, so is \( f \) (Proposition 8.6), hence

\[
|A| = \deg f = \deg \bar{f} = |\bar{A}|.
\]

It follows that \( \phi|_A \) is a bijection of \( A \) on \( \bar{A} \) and so invertible. We deduce that \( \sigma|_A \) is the identity on \( A \), which implies that \( \sigma \) is the identity of the Galois group of \( f \). We have established that \( \Psi \) is free.

We now consider the transitivity. Let us fix \( \phi \in Hom(D,K) \) and note \( N \) the cardinal of the Galois group \( G = Gal(E/\mathbb{Q}) \), where \( E \) is a fixed splitting field of \( f \). We write \( O \) for the orbit of \( \phi \):

\[
O = \{ \sigma.\phi : \sigma \in G \}.
\]

As the action \( \Psi \) is free, we have \( |O| = N \). We aim to show that \( O = Hom(D,K) \). Let us write \( \phi_1, \ldots, \phi_N \) for the homomorphisms in \( O \). If \( O \neq Hom(D,K) \), then there exists \( \phi_{N+1} \in Hom(D,K) \setminus O \). We may consider the homomorphisms as characters of the monoïde \( (D,\cdot) \) into \( K \). We have

\[
N = |Gal(E/\mathbb{Q})| = |E : \mathbb{Q}| = \text{rk} \; D.
\]
(For the last equality see Proposition 8.3.) Hence there is a basis \((u_i)\) of \(D\) whose cardinal is \(N\). The system
\[
\begin{align*}
x_1 \phi_1(u_1) + \cdots + x_{N+1} \phi_{N+1}(u_1) &= 0 \\
& \vdots \\
x_1 \phi_1(u_N) + \cdots + x_{N+1} \phi_{N+1}(u_N) &= 0
\end{align*}
\]
is composed of \(N\) equations and \(N+1\) unknowns, therefore has a nonzero solution \((\lambda_1, \ldots, \lambda_{N+1})\).

If \(a \in D\) and \(a = \sum_{j=1}^{N} a_j u_j\), then
\[
\sum_{i=1}^{N+1} \lambda_i \phi_i(a) = \sum_{i=1}^{N+1} \lambda_i \phi_i \left( \sum_{j=1}^{N} a_j u_j \right) = \sum_{i=1}^{N} \lambda_i \sum_{j=1}^{N} a_j \phi_i(u_j) = \sum_{j=1}^{N} \sum_{i=1}^{N+1} \lambda_i \phi_i(u_j) = 0.
\]

Therefore \(\sum_{i=1}^{N+1} \lambda_i \phi_i(a) = 0\), for all \(a \in D\), which contradicts Dedekind’s lemma (Theorem 8.1). It follows that \(O = \text{Hom}(D, K)\) and therefore that the action \(\Psi\) is transitive. \(\square\)

We may now prove the principal result of this section. This is particularly important, in that it often gives us important information concerning the Galois group of certain polynomials. It is often referred to as Dedekind’s Theorem.

**Theorem 8.3** Let \(f \in \mathbb{Z}[X]\) be monic and \(p\) a prime number. If \(\bar{f}\), the reduction of \(f\) modulo \(p\), is strongly separable, then there is an injective group homomorphism \(g\) of the Galois group of \(\bar{f}\), \(\bar{G} = \text{Gal}(K/F_p)\), into the Galois group of \(f\), \(G = \text{Gal}(E/Q)\).

**Proof** As in Section 7.4, we note \(\pi\) the standard projection of \(D\) on \(K\). Then \(\bar{\sigma} \circ \pi \in \text{Hom}(D, K)\), for all \(\bar{\sigma}\) in the Galois group \(\bar{G}\). As the action \(\Psi\) of the previous proposition is free and transitive, there exists a unique \(\tau \in G\) such that
\[
\bar{\sigma} \circ \pi = \tau \circ \pi = \pi \circ \tau.
\]
We define \(g(\bar{\sigma}) = \tau\) and so obtain a mapping from \(\bar{G}\) into \(G\). In fact, \(g\) is an injective group homomorphism, as we now see. First,
\[
\begin{align*}
\pi \circ g(\bar{\sigma}_1 \circ \bar{\sigma}_2) &= (\sigma_1 \circ \sigma_2) \circ \pi = \sigma_1 \circ (\sigma_2 \circ \pi) \\
&= \sigma_1 \circ (\pi \circ g(\bar{\sigma}_2)) = (\bar{\sigma}_1 \circ \pi) \circ g(\bar{\sigma}_2) \\
&= (\pi \circ g(\bar{\sigma}_1)) \circ g(\bar{\sigma}_2) = \pi \circ (g(\bar{\sigma}_1) \circ g(\bar{\sigma}_2)).
\end{align*}
\]
As the action \(\Psi\) is free,
\[
g(\bar{\sigma}_1 \circ \bar{\sigma}_2) = g(\bar{\sigma}_1) \circ g(\bar{\sigma}_2),
\]
i.e., \(g\) is a homomorphism. In addition,
\[
g(\bar{\sigma}) = \text{id}_G \implies \bar{\sigma} \circ \pi = \pi.
\]
Let \( x \in K \). As \( \pi \) is surjective, there exists \( y \in D \) such that \( \pi(y) = x \), so \( \bar{\sigma} \circ \pi(y) = \pi(x) \), i.e., \( \pi(x) = x \). Hence, \( \bar{\sigma} = \text{id}_G \). It follows that \( g \) is injective.

**Remark** We have fixed the splitting field of \( f \) over \( \mathbb{Q} \) (resp. \( \bar{f} \) over \( \mathbb{F}_p \)) to obtain a given Galois group of \( f \) (resp. \( \bar{f} \)). Changing the splitting fields and thus the Galois groups does not of course affect the result above, because all Galois groups of a given polynomial over a certain field are isomorphic.

From the theorem which we have just proved, for a root \( \alpha \) of \( f \), we obtain the relation

\[
\gamma(g(\bar{\sigma})(\alpha)) = \bar{\sigma}(\gamma(\alpha)),
\]

where \( \gamma \) is the mapping \( \pi \) restricted to \( A \). \( \gamma \) is an invertible function from \( A \) into \( \bar{A} \), since \( \bar{f} \) is strongly separable. Indeed, as a function from \( A \) into \( \bar{A} \), \( \gamma \) is surjective and the fact that \( \bar{f} \) is strongly separable ensures that \( A \) and \( \bar{A} \) have the same cardinality. Thus on \( A \) we have

\[
\gamma \circ g(\bar{\sigma}) = \bar{\sigma} \circ \gamma \implies g(\bar{\sigma}) = \gamma^{-1} \circ \bar{\sigma} \circ \gamma.
\]

From Section 7.7 we know that the Galois group \( \bar{G} = \text{Gal}(K/\mathbb{F}_p) \) is generated by the Frobenius automorphism \( Fr : x \mapsto x^p \) and is composed of cycles whose length correspond to the degrees of the irreducible polynomials in the decomposition of the reduced polynomial \( \bar{f} \). From the relation \( g(\bar{\sigma}) = \gamma^{-1} \circ \bar{\sigma} \circ \gamma \), we obtain a permutation in the Galois group of \( G = \text{Gal}(E/\mathbb{Q}) \) with the same cycle structure. By varying the value of the prime \( p \) we may find sufficient permutations to characterize the Galois group of \( f \).

**Example** If \( f(X) = 3 + X + X^4 + X^6 \), then the factorizations of the reductions of \( f \) modulo 2 and 3 are

\[
\bar{f}(X) = (1 + X)(1 + X + X^2)(1 + X + X^3) \quad \text{and} \quad \bar{f}(X) = X(2 + X)(2 + 2X + 2X^2 + X^3 + X^4).
\]

The reductions have no multiple roots and so are strongly separable. Applying the theorem, we see that \( G \) has elements \( \sigma \) and \( \tau \) such that \( \sigma|_A \) is a permutation with the cycle structure \((1, 2, 3)\) (a product of a 2-cycle and a 3-cycle) and \( \tau|_A \) a permutation with the cycle structure \((1, 1, 4)\) (a 4-cycle). Going a little further, we find that the reduction modulo 5 has the form

\[
\bar{f}(X) = (3 + X)^2(2 + X + 3X^2 + 4X^3 + X^4)
\]

This has a factor which is a square and hence a multiple root, so we cannot apply the theorem.
Chapter 9

Determination of the Galois group

In general, it is difficult to determine the Galois group of a polynomial. However, we can often find certain properties of the group. In some cases this may be enough to determine the group. We will mostly consider irreducible rational polynomials.

9.1 Inclusion in an alternating group \( A_n \)

We have seen that a Galois group \( G \) of a polynomial having \( n \) distinct roots may be considered as a subgroup of the permutation group \( S_n \). It is natural to ask whether permutations of this group are even, i.e., if \( G \subset A_n \). We will begin with a criterion applying to this question.

**Proposition 9.1** Let \( F \) be a field whose characteristic is not 2 and \( f \in F[X] \) strongly separable of degree \( n \). Then the Galois group \( G \) of \( f \) is isomorphic to a subgroup of \( A_n \), the alternating group of order \( n \), if and only if the discriminant of \( f \), \( \Delta(f) \), is a square in \( F \).

**Proof** Let \( A = \{ \alpha_1, \ldots, \alpha_n \} \) be the set of roots of \( f \) in a splitting field \( E \) of \( f \) and \( \delta(f) = \prod_{1 \leq i < j \leq n} (\alpha_i - \alpha_j) \). As \( f \) is strongly separable, \( \delta(f) \neq 0 \). Also, \( \delta(f) \in F(\alpha_1, \ldots, \alpha_n) \) and \( \delta(f)^2 = \Delta(f) \in F \). To shorten the notation let us write \( \delta \) for \( \delta(f) \) and \( \Delta \) for \( \Delta(f) \). Clearly, \( \Delta \) is a square in \( F \) if and only if \( \delta \in F \).

We now take \( \sigma \in \text{Gal}(F(\alpha_1, \ldots, \alpha_n)/F) \). If \( \epsilon_\sigma = \pm 1 \) is the sign of the permutation \( \sigma = \sigma|_A \) of \( A \), then

\[
\sigma(\delta) = \prod_{1 \leq i < j \leq n} (\alpha_{\sigma(i)} - \alpha_{\sigma(j)}) = \epsilon_\sigma \prod_{1 \leq i < j \leq n} (\alpha_i - \alpha_j) = \epsilon_\sigma \delta,
\]

hence \( \sigma(\delta) = \pm \delta \). As \( \text{char } F \neq 2 \), we have \( \delta \neq -\delta \) and so \( \sigma(\delta) = \delta \) if and only if the permutation \( \sigma \) is even, or, identifying \( A \) with \( \mathbb{N}_n = \{1, \ldots, n\} \), if and only if \( \sigma \in A_n \). We thus obtain that the Galois group \( G \) fixes \( \delta \) if and only if \( G \subset A_n \), or equivalently, by Theorem 6.2, \( \delta \in F \) if and only \( G \subset A_n \). As \( \Delta \) is a square in \( F \) if and only if \( \delta \in F \), this finishes the proof. \( \Box \)

**Example** Let \( f \in F[X] \) be separable, irreducible and of degree 3. From Theorem 7.2, 3 divides the cardinal of the Galois group \( G \) of \( f \) over \( \mathbb{Q} \). If we now suppose that \( \Delta \) is a square, then, identifying \( G \) with a subgroup of \( S_n \), we have \( G \subset A_3 \). However, as \( |A_3| = 3 \), we have \( G \) isomorphic to \( A_3 \). If, on the other hand, \( \Delta(f) \) is not a square in \( F \), then \( G \not\subset A_3 \). The only other subgroup of \( S_3 \) divisible by 3 is \( S_3 \) itself, so in this case \( G \) is isomorphic to \( S_3 \).
We will now consider another criterion which enables us to determine the nature of the Galois group, but this time only over $\mathbb{Q}$.

### 9.2 A criterion for rational polynomials

In the last section we considered a criterion which was generally applicable. Often criteria can only be used for certain types of field. This is the case with the criterion which we now consider. We will first need to do a little preliminary work on permutations.

**Lemma 9.1** If $p$ is a prime number, then every element of $S_p$ of order $p$ is a $p$-cycle.

**Proof** Let $\pi \in S_p$ be of order $p$. We may write

$$\pi = \pi_1 \cdots \pi_r,$$

where the $\pi_i$ are nontrivial disjoint cycles. We have

$$p = o(\pi) = [o(\pi_1), \ldots, o(\pi_r)].$$

Hence, $o(\pi_i)|p$, for all $i$. As $o(\pi_i) > 1$, we must have $o(\pi_i) = p$. This implies that all the $\pi_i$ are $p$-cycles and so $\pi$ is a product of $p$-cycles. However, we cannot have more than one such cycle, because the permutation is on $p$ elements. Therefore, $\pi$ is a $p$-cycle. \(\square\)

It is well-known that the transposition $(1\ 2)$ and the $n$-cycle $(1\ldots n)$ generate $S_n$. This is not in general true for any transposition and $n$-cycle. For example, the cycles $(1\ 3)$ and $(1\ 2\ 3\ 4)$ in $S_4$ generate a subgroup $G$ isomorphic to $D_8$. To see this, it is sufficient to notice that $G$ is a nonabelian group of cardinal 8, with an element of order 4 and an element of order 2 (see Appendix B). However, if $n$ is prime, then any transposition and $n$-cycle generate $S_n$. We will prove a related result and then establish this as a corollary.

**Proposition 9.2** For $1 \leq a < b \leq n$, the transposition $(a\ b)$ and the $n$-cycle $(1\ 2\ldots n)$ generate $S_n$ if and only if $(b-a,n) = 1$.

**Proof** Let $d = (b-a,n)$. We claim that if $\pi \in \langle(a\ b), (1\ 2\ldots n)\rangle$, then

$$i \equiv j \pmod{d} \implies \pi(i) \equiv \pi(j) \pmod{d}.$$ 

To prove this, it is sufficient to consider the cases where $\pi = (a\ b)$ and $\pi = (1\ 2\ldots n)$. We have

- for $i \neq a, b$, $(a\ b)(i) = i$;
- for $i = a$, $(a\ b)(i) = b$;
- for $i = b$, $(a\ b)(i) = a$.

From these equalities, we see that, if $\pi = (a\ b)$, then

$$d|(j-i) \implies d|\pi(i) - \pi(j),$$

i.e., the assertion is true for $\pi = (a\ b)$. Now let us consider the case where $\pi = (1\ 2\ldots n)$. We have

$$\pi(i) = i + 1 \pmod{n} \implies \pi(i) = i + 1 \pmod{d},$$

80
because \(d\mid n\). As

\[ i \equiv j \pmod{d} \implies i + 1 \equiv j + 1 \pmod{d}, \]

the assertion is true for \(\pi = \langle 1 \ 2 \ \ldots \ n \rangle\). We have proved the claim.

Now suppose that \(d > 1\) and consider the transposition \((1 \ 2)\). We have

\[
(1 \ 2)(1) = 2 \quad \text{and} \quad (1 \ 2) = 1 + d.
\]

However, \(1 \equiv 1 + d \pmod{d}\), but \(2 \not\equiv 1 + d \pmod{d}\). Hence, \((1 \ 2) \notin \langle (a \ b), (1 \ 2 \ldots n) \rangle\). Therefore \(S_n\) is not generated by \((a \ b)\) and \((1 \ 2 \ldots n)\).

We now prove the converse. Let \(\sigma = (1 \ 2 \ldots n)\); then \(\sigma^n(a) \equiv a + i \pmod{n}\). Hence

\[
\sigma^{b-a}(a) \equiv b \pmod{n}.
\]

As \(1 \leq \sigma^{b-a}(a), b \leq n\), we have \(\sigma^{b-a}(a) = b\). Next we notice that there exist \(s\) and \(t\) such that \(s(b - a) + tn = 1\), because \(b - a\) and \(n\) are coprime. This implies that

\[
\sigma = \sigma^{(b-a)s} \sigma^{nt} = \sigma^{(b-a)s} \implies \langle (a \ b), \sigma \rangle = \langle (a \ b), \sigma^{b-a} \rangle.
\]

Now \(\sigma^{b-a}\) is an \(n\)-cycle. If this is not the case, then \(\sigma^{b-a}\) can be written as a product of disjoint cycles of length less than \(n\). However,

\[
\sigma^{\sigma^{b-a}(1)} \equiv 1 + \alpha(b-a) \equiv 1 \pmod{n} \implies n|\alpha(b-a) \implies n|\alpha,
\]

because \((b-a,n) = 1\). If \(1 \leq \alpha < n\), then this is not possible, so \(\sigma^{\sigma^{b-a}(1)} \neq 1\). This means that \(1\) belongs to no cycle of length smaller than \(n\) and so \(\sigma^{b-a}\) is an \(n\)-cycle.

There exists a permutation \(\pi \in S_n\) such that \(\pi(1 \ 2 \ldots n)\pi^{-1} = \sigma^{b-a}\) and \(\pi(1) = a, \pi(2) = b\). Then

\[
S_n = \pi S_n \pi^{-1} = \pi \langle (1 \ 2), (1 \ 2 \ldots n) \rangle \pi^{-1} = \langle \pi(1 \ 2) \pi^{-1}, \pi(1 \ 2 \ldots n) \pi^{-1} \rangle = \langle (a \ b), \sigma^{b-a} \rangle = \langle (a \ b), \sigma \rangle.
\]

This finishes the proof.

**Lemma 9.2** Let \(p\) be a prime number. If \(\tau\) is a transposition and \(\sigma\) a \(p\)-cycle in \(S_p\), then \(H = \langle \tau, \sigma \rangle\), the subgroup of \(S_p\) generated by \(\tau\) and \(\sigma\), is the whole group \(S_p\).

**Proof** Let \(\tau = (a \ b)\). There is a permutation \(\pi \in S_p\) such that \(\pi(1 \ 2 \ldots p)\pi^{-1} = \sigma\). Let \(\tau = (a \ b)\) and \(\pi(a') = a, \pi(b') = b\). Then we have

\[
S_p = \pi \langle (a' \ b'), (1 \ 2 \ldots p) \rangle \pi^{-1},
\]

because \((b' - a', p) = 1\) (Proposition 9.2). Now

\[
\pi((a' \ b'), (1 \ 2 \ldots p)) \pi^{-1} = \langle \pi(a' \ b') \pi^{-1}, \pi(1 \ 2 \ldots p) \pi^{-1} \rangle = \langle (a \ b), \sigma \rangle = \langle \tau, \sigma \rangle.
\]

We have proved what we set out to establish.

We now turn to a result which enables us to determine the Galois group of a rational polynomial under certain conditions.
Theorem 9.1 Let \( f \in \mathbb{Q}[X] \) be irreducible and of prime degree \( p \). If \( f \) has only two complex roots, \( \alpha \) and \( \bar{\alpha} \), then the Galois group \( G \) of \( f \) over \( \mathbb{Q} \) is isomorphic to \( S_p \).

Proof From Lemma 9.2, it is sufficient to show that \( G \) has a transposition and a \( p \)-cycle. The mapping conjugation restricted to the set of roots of \( f \) is a transposition. Also, from Theorem 7.2, \( p|G \), so \( G \) has an element of order \( p \). From Lemma 9.1, this must be a \( p \)-cycle. This finishes the proof. \( \square \)

Example The polynomial \( f(X) = -1 + X + X^3 \) is irreducible over \( \mathbb{Q} \). If \( f \) is reducible over \( \mathbb{Q} \), then \( f \) is also reducible over \( \mathbb{Z} \) and, in this case, \( f \), the reduction of \( f \) modulo 2, has a root in \( \mathbb{Z}_2 \). However, this is not the case, and so \( f \) is irreducible over \( \mathbb{Q} \). Also, \( f'(X) = 1 + 3X^2 \), which does not vanish in \( \mathbb{R} \), so \( f \) has a unique root in \( \mathbb{R} \). This means that \( f \) has a pair of complex roots and we may apply the theorem: the Galois group of \( f \) is isomorphic to \( S_3 \).

Example The polynomial \( f(X) = -1 - 4X + X^5 \) is irreducible over \( \mathbb{Q} \). To see this it is sufficient to show that \( f \), the reduction of \( f \) modulo 2, is irreducible. This is so, because \( f \) has no root in \( \mathbb{Z}_2 \) and no polynomial of degree 2 in \( \mathbb{Z}_2[X] \) divides \( f \). The derivative of \( f \) is \( f'(X) = -4 + 5X^4 \). As a function defined on \( \mathbb{R} \), \( f \) is positive for \( x^4 \geq \frac{4}{5} \) and negative for \( x^4 \leq \frac{4}{5} \). As \( f(0) = -1 \), \( f(-1) = 2 \) and \( \lim_{x \to \pm \infty} f(x) = \pm \infty \), \( f \) has precisely three real roots. Applying the theorem, we see that the Galois group of \( f \) is isomorphic to \( S_3 \).

We will now look at a more general polynomial. Let \( p \) be a prime number, with \( p \geq 7 \), and \( m, n_1, \ldots, n_{p-2} \) positive even integers such that \( n_i < n_{i+1} \) and \( \sum_{i=1}^{p-2} n_i^2 - 2m < 0 \). We define the polynomial \( g \in \mathbb{Z}[X] \) by

\[
g(X) = (m + X^2)(-n_1 + x)(-n_2 + X) \cdots (-n_{p-2} + X).
\]

The polynomial \( g \) has the roots \( n_1, \ldots, n_{p-2} \). On an interval \( (n_i, n_{i+1}) \subset \mathbb{R} \) the sign of the polynomial function \( g \) does not change, because there is no real root in such an interval. Also, as \( g'(n_i) \neq 0 \), the signs of \( g \) on adjacent intervals are opposites. Thus \( g \) has \( \frac{p-1}{2} \) positive relative maxima and \( \frac{p-2}{2} \) negative relative maxima. If \( k \) is an odd integer, then it is not difficult to see that \( |g(k)| > 2 \), hence the relative maxima have a value strictly superior to 2.

We now set \( f(X) = g(X) - 2 \). From what we have seen, there exist \( x_1, \ldots, x_{p-2} \in (n_1, n_{p-2}) \) such that for the polynomial function \( f \) we have \( f(x_i) f(x_{i+1}) < 0 \), for \( i = 1, \ldots, p-4 \). Therefore \( f \) has a root in each interval \( (x_i, x_{i+1}) \). As \( f(n_i) = -2 \), and \( f(x_1) \) and \( f(x_{p-3}) \) have opposite signs, there must exist a root of \( f \) in \( (n_1, x_1) \) or in \( (x_{p-3}, n_{p-2}) \). In addition, as \( f(n_{p-2}) = -2 \) and \( \lim_{x \to \pm \infty} f(x) = \pm \infty \), we have another root of \( f \) in the interval \( (n_{p-2}, \infty) \). We have shown that \( f \) has at least \( p - 2 \) real roots.

We will now show that \( f \) has two roots in \( \mathbb{C} \setminus \mathbb{R} \). We have

\[
f(X) = (X + i\sqrt{m})(X - i\sqrt{m})(-n_1 + X)(-n_2 + X) \cdots (-n_{p-2} + X) - 2
\]

and the constant term is not divisible by 4 and

\[
f(X) = \prod_{i=1}^{p}(-\alpha_i + X),
\]

where the \( \alpha_i \) are the complex roots of \( f \). If we compare the coefficients of \( X^{p-1} \) and \( X^{p-2} \) in the two expressions for \( f \), then we obtain

\[
\sum_{i=1}^{p} \alpha_i = \sum_{i=1}^{p-2} n_i \quad \text{and} \quad \sum_{i<j} \alpha_i \alpha_j = \sum_{i<j} n_i n_j + m.
\]
Hence

\[ \sum_{i=1}^{p} \alpha_i^2 = \left( \sum_{i=1}^{p} \alpha_i \right)^2 - 2 \sum_{i<j} \alpha_i \alpha_j = \left( \sum_{i=1}^{p-2} n_i \right)^2 - 2 \sum_{i<j} n_in_j + m = \sum_{i=1}^{p-2} n_i^2 - 2m. \]

As \( \sum_{i=1}^{p-2} n_i^2 - 2m < 0 \), we have \( \sum_{i=1}^{p} \alpha_i^2 < 0 \), so at least one \( \alpha_i \in \mathbb{C} \setminus \mathbb{R} \). However, as \( f \) is a real polynomial, the complex conjugate of \( \alpha_i \) is also a root of \( f \). We have shown that \( f \) has only real roots except for a pair of complex conjugates.

To complete the discussion we show that \( f \) is irreducible over \( \mathbb{Q} \). Now, all the coefficients of \( f \), except the leading coefficient, are divisible by 2 and the constant term is not divisible by 4 (4|\( mn_1 \cdots n_{p-2} \Rightarrow 4 (mn_1 \cdots n_{p-2} - 2) \)). From Eisenstein’s criterion, \( f \) is irreducible over \( \mathbb{Q} \).

We may now apply Theorem 9.1 to see that for the class of polynomials under consideration the Galois group is \( S_p \). It is worth noticing that there is an infinite number of polynomials in this class.

### 9.3 Possible forms of the Galois group

As we have seen, the Galois group of a polynomial \( f \) of degree \( n \) may be considered as a subgroup of \( S_n \). However, not all subgroups of \( S_n \) are possible. If we suppose that \( f \) is separable and irreducible, then the Galois group of \( f \) must be transitive and its cardinal a multiple of \( n \) (Theorem 7.2). Therefore, if we are considering such polynomials, then we know that the Galois group must belong to a certain finite subclass of subgroups of \( S_n \). For example, if \( f \in \mathbb{Q}[X] \) is irreducible and of degree 5 and \( G \) is its Galois group, then \( 5|\vert G \vert \). If we also know that the discriminant of \( f \) is a square in \( \mathbb{Q} \), then we can say that \( G \) is a subgroup of \( A_n \) (Proposition 9.1). This limits considerably the possibilities.

Now we aim to consider the Galois group \( G \) of a an irreducible rational polynomial of degree \( n \). If \( n = 2 \) and \( \vert S_n \vert = 2 \), in this case there can only be one possibility for the Galois group, namely \( S_2 \). Let us now consider the case where \( n = 3 \). We have already seen (in the first section of this chapter) that there are two possibilities, namely \( S_3 \) and \( A_3 \), the first when the discriminant of the polynomial is not a square in \( \mathbb{Q} \) and the other when it is. We now turn to the case where \( n = 4 \). This is more instructive and we will need some elementary group theory. We recall that the only subgroup of \( S_4 \) of index 2 is \( A_4 \).

#### Transitive subgroups of \( S_4 \) divisible by 4

Now let us consider the possible Galois groups for irreducible rational polynomials of degree 4. We must find the subgroups of \( S_4 \) which are transitive and whose cardinal is divisible by 4. The possible orders for such subgroups are \( 4, 8, 12 \) and \( 24 \). The only subgroup of order 24 is \( S_4 \) and the only subgroup of order 12 is \( A_4 \). Therefore we are left with subgroups of order 4 and 8.

If \( G \) is a subgroup of order 8, then \( G \) must be a Sylow 2-subgroup of \( S_4 \). All such subgroups are conjugate and hence isomorphic. Thus, up to isomorphism, there is only one possible subgroup of order 8. If we set

\[
\rho = (1\ 2\ 3\ 4) \quad \text{and} \quad \sigma = (1\ 3),
\]

then we find that

\[
\sigma \rho \sigma^{-1} = (1\ 4\ 3\ 2) = \sigma^{-1}
\]

and that the set

\[
S = \{e, \rho, \rho^2, \rho^3, \sigma, \rho\sigma, \rho^2\sigma, \rho^3\sigma\}
\]

83
is a group (generated by $\rho$ and $\sigma$). This group is thus isomorphic to the dihedral group $D_8$.

Finally we turn to the case where the subgroup $G$ is of order 4. Clearly the subgroup generated by a 4-cycle is a transitive subgroup of $S_4$ of order 4 and all such subgroups are isomorphic. The other subgroups of $S_4$ of order 4 are isomorphic to the Klein subgroup, i.e., $\mathbb{Z}_2 \times \mathbb{Z}_2$. In addition to the identity, such a group has elements of order 2 of cycle types $(2, 1, 1)$ or $(2, 2)$. There are three possibilities:

- All the $\sigma_i$ are transpositions: then we must have $(1\ 2), (1\ 3)$ and $(2\ 3)$ and the product of the first two is the 3-cycle $(1\ 3\ 2)$, a contradiction.
- One of the $\sigma_i$ is of type $(2, 2)$ and the other two are transpositions: in this case, the two transpositions must be disjoint, otherwise their product is a 3-cycle and the group has the form
  \[ \{e, (1\ 2), (3\ 4), (1\ 2)(3\ 4)\}, \]
  which is not transitive.
- Two of the $\sigma_i$ are of type $(2, 2)$, which implies that the third is also of this type and the group has the form
  \[ \{e, (1\ 2)(3\ 4), (1\ 3)(2\ 4), (1\ 4)(2\ 3)\}, \]
  which we note $V_4$. This subgroup is clearly transitive.

We are now going to consider transitive subgroups of $S_5$. However, before doing so, we need to introduce a little group theory.

We recall that a group is simple if it has no proper normal subgroup other than $\{e\}$. For $n \geq 5$, $A_n$ is simple. (A proof of this may be found, for example, in [19].)

**Exercise 9.1** Show that $A_4$ is not simple. What can we say about $A_2$ and $A_3$?

**Exercise 9.2** Show that, for $n \geq 5$, $A_n$ is the unique nontrivial normal subgroup of $S_n$.

We need a technical result, which is not standard.

**Proposition 9.3** If $G$ is a finite group and $H$ a nontrivial subgroup such that $|G|$ does not divide $[G : H]$, then $H$ contains a nontrivial normal subgroup of $G$.

**Proof** Let $n = [G : H]$. Each $g \in G$ induces a permutation $\pi_g$ on the quotient set $G/H$:

\[ \pi_g(xH) = gxH. \]

As $[G : H] = n$, we may identify $\pi_g$ with an element of $S_n$. The mapping $\phi : g \mapsto \pi_g$ is a homomorphism:

\[ \pi_{gh}(xH) = ghxH = \pi_g(hxH) = \pi_g \circ \pi_h(xH). \]

Now $\ker \phi$ is a normal subgroup of $G$ contained in $H$:

\[ gxH = H \iff xH = g^{-1}H. \]

As this is true for all $x \in G$, it is true for the identity element, so we obtain

\[ eH = g^{-1}H \iff g^{-1} \in H \iff g \in H, \]

84
and it follows that $\ker \phi \subset H$.

Also
\[
G/\ker \phi \simeq \text{Im} \phi \implies |G/\ker \phi||n! \implies |G||\ker \phi||n!
\]
If $|G|$ does not divide $n!$, then $|\ker \phi| \neq 1$ and so $\ker \phi$ is not trivial.

The knowledge of semidirect products needed in the next part of our exposition can be found in Appendix B.

**Transitive subgroups of $S_5$ divisible by 5**

Now let us consider the possible Galois groups for irreducible rational polynomials of degree 5. The orders of such groups must be multiples of 5 and divisors of 120. In fact, the transitivity does not enter into the question.

**Proposition 9.4** Let $G$ be a subgroup of $S_5$ whose order is divisible by 5. Then $G$ is transitive.

**Proof** By Cauchy’s Theorem $G$ contains an element of order 5, i.e., a 5-cycle $\sigma = (x_1, \ldots, x_5)$. It is not difficult to see there is a power $k$ of $\sigma$ which sends $x_i$ to $x_j$, for any pair of numbers $x_i$ and $x_j$. Therefore $G$ is transitive.

**Remark** We can generalize this result to $S_p$, for any prime $p$: If $p$ is a prime number and $G$ a subgroup of $S_p$ such that $p||G|$, then $G$ is transitive.

Taking into account what we have seen, the possible orders of subgroups of $S_5$ which interest us are 5, 10, 15, 20, 30, 40, 60 and 120.

Let us first consider the possible cyclic subgroups. In $S_5$ the highest possible order of an element is 6; this results from the decomposition of a permutation into distinct cycles. It follows that the only cyclic groups of $S_5$ whose order is divisible by 5 are those generated by a 5-cycle.

Now we consider subgroups of order 10. If $G$ is such a subgroup, then it is cyclic or isomorphic to $D_{10}$ (Proposition C.4). The first possibility has already been ruled out, so there only remains the second. This occurs: If we set $\sigma = (1\ 2\ 3\ 4\ 5)$ and $\tau = (1\ 3)(4\ 5)$ and then $G \simeq \langle \sigma, \tau \rangle$. If we set $H = \langle \sigma \rangle$ and $K = \langle \tau \rangle$, then it is easy to check that $G$ is isomorphic to the semidirect product of $H$ and $K$, which is not direct.

Suppose that $G$ is a subgroup of $S_5$ of order 15. From Theorem C.2, $G$ is cyclic, which is impossible, so there is no subgroup of order 15 in $S_5$.

We now turn to the case where $|G| = 20$. This is a little more interesting. $G$ has a Sylow 5-subgroup $P$ and a Sylow 2-subgroup $Q$, with $|P| = 5$ and $|Q| = 4$. Writing $s_5$ for the number of Sylow 5-subgroups, we have $s_5|4$ and so $s_5$ can take the values 1, 2 or 4. However, $s_5 \equiv 1 (\mod 5)$, so the only possibility is $s_5 = 1$. This implies that $P$ is normal in $G$. As the order of elements in $P$ and $Q$ are coprime $P \cap Q = \{e\}$ and so $PQ = G$. If $Q$ is normal in $P$, then $G$ is the direct product of $P$ and $Q$ and so abelian. However, in this case $G$ has an element of order 10, which we have excluded, so $G$ is a semidirect product of $P$ and $Q$, which is not abelian.

We would like to know a little more about the subgroup $Q$. We consider the mapping
\[
\phi : Q \longrightarrow \text{Aut}(P), y \longmapsto \phi_y,
\]
where
\[
\phi_y(x) = yxy^{-1},
\]
for all $x \in P$. If $a$ is a generator of $P$ and $y \in \ker \phi$, then

$$yay^{-1} = a \implies ya = ay.$$ 

As $y$ and $a$ commute, we have $o(ya) = o(y)o(a)$, since the orders of $y$ and $a$ are coprime. If $o(y) = 2$, then $o(ya) = 10$, and if $o(y) = 4$, then $o(ya) = 20$, both of which are impossible. Therefore $o(y) = 1$, which implies that $y = e$. Thus $\phi$ is injective. As $\text{Aut}(P) \cong \mathbb{Z}_4$, $Q \cong \mathbb{Z}_4$ and $Q$ is cyclic. It is a simple matter to check the subgroup of $S_5$ generated by the cycles $(1\ 2\ 3\ 4\ 5)$ and $(2\ 3\ 5\ 4)$ is a subgroup of order 20 of the required type.

What about subgroups $G$ of order 30. The index $[S_5 : G]$ of such a subgroup is 4 and 120, the cardinal of $S_5$ does not divide $24 = 4!$, so, from Proposition 9.3, $G$ contains a nontrivial normal subgroup $N$ of $S_5$. However, the only nontrivial normal subgroup of $S_5$ is $A_5$ (Exercise 9.2). Thus $N = A_5$, which is impossible, because $|N| < |A_5|$. So there is no subgroup of order 30. We may use an analogous argument to show that there is no subgroup of order 40.

Finally we come to subgroups of order 60 or 120. In the first case there is only $A_5$ and in the second $S_5$ itself.

The following theorem sums up our work on the transitive subgroups of $S_4$ and $S_5$:

**Theorem 9.2** For $S_4$ and $S_5$ we have

- The transitive subgroups of $S_4$ of order divisible by 4 are $S_4$, $A_4$, $D_8$, subgroups generated by a 4-cycle and $V_4$.

- The (transitive) subgroups of $S_5$ of order divisible by 5 are $S_5$, $A_5$, $D_{10}$, subgroups generated by a 5-cycle and subgroups isomorphic to the nonabelian semidirect product of $\mathbb{Z}_5$ and $\mathbb{Z}_4$.

The examples of $S_4$ and $S_5$ show the difficulty in determining those subgroups of $S_n$ which can be Galois groups of irreducible rational polynomials of degree $n$. Determining whether such subgroups are actually Galois groups of an irreducible rational polynomial of degree $n$ is another problem. We will come back to this question presently.

In the cases we have considered, the absence of abelian groups has probably been observed. This is not an accident, as we will soon see. We recall that if the group $G$ acts on the set $X$, then the stabiliser $G_x$ of $x \in X$ is defined as

$$G_x = \{g \in G : g.x = x\}$$

and the orbit $O_x$ of $x$ as

$$O_x = \{g.x : g \in G\}.$$ 

The orbit-stabilizer theorem asserts, that if $G$ is finite, then

$$|O_x| = \frac{|G|}{|G_x|}.$$ 

We say that the action is transitive, if for any pair $x, y \in X$, there is a $g \in G$ such that $g.x = y$.

If $G$ is a group of permutations on a set $X$, then there is a natural action of $G$ on $X$ defined by

$$g.x = g(x),$$

for all $g \in G$ and $x \in X$. We will be interested here in the case where $G \subset S_n$ and $X = N_n = \{1, \ldots, n\}$. 

86
**Proposition 9.5** If $G \subset S_n$ is transitive and abelian, then $|G| = n$.

**Proof** From the orbit-stabilizer theorem we have

$$|O_x| = \frac{|G|}{|G_x|}.$$  

As $G$ is transitive, the action of $G$ on $N_n$ is transitive and so, for any $x \in N_n$,

$$|O_x| = n \implies |G| = n|G_x|.$$  

We claim that $|G_x| = 1$. Let $g \in G_x$ and take $a \in N_n$. As $G$ is transitive, there exists $h \in G$ such that $h.x = a$. Hence, using the fact that $G$ is abelian,

$$g.a = g.(h.x) = h.(g.x) = h.x = a.$$  

As this equality is true for any $a \in N_n$, $g = e$, which proves our claim. We obtain $|G| = n$.  

**Corollary 9.1** If $p$ is a prime number, and $G$ is a transitive abelian subgroup of $S_p$, then $G$ is generated by a $p$-cycle.

**Proof** This is a consequence of Proposition 9.5 and Lemma 9.1.  

We now return to the question of the existence of an irreducible rational polynomial of degree $n$ whose Galois group is isomorphic to a given transitive subgroup of $S_n$. For $S_n$ itself the answer is always positive.

We now consider the case where $n = 4$.

- If $f(X) = -2 + X^4$, then the Galois group of $f$ is $D_8$. We give a proof of this in Appendix D.

- From Theorem 7.7 we know that the Galois group $G = \text{Gal}(\mathbb{Q}(\zeta_5)/\mathbb{Q})$ is isomorphic to $C_5^*$, which is in turn isomorphic to $C_4$. However, $\mathbb{Q}(\zeta_5)$ is a splitting field of $\Phi_5(X) = 1 + X + X^2 + X^3 + X^4$, which is irreducible. Thus the Galois group of $\Phi_5$ is isomorphic to $C_4$ and so must be generated by a 4-cycle.

- For $V_4$ we have the following argument. The splitting field of $g(X) = 1 + X^4$ is $\mathbb{Q}(i, \sqrt{2})$, which is also the splitting field of $h(X) = (1 + X^2)(-2 + X^2)$. However, the Galois group of $h$ is isomorphic to $C_2 \times C_2$ (see Example 1 in the next section), so this must be the case for $g$. Given that $V_4$ is the only transitive subgroup of $S_4$ isomorphic to $C_2 \times C_2$, $V_4$ must be isomorphic to the Galois group of $g$.

- Finally we consider $A_4$. We will show that this group is isomorphic to the Galois group of $k(X) = 12 + 8X + X^4$. First we notice that the discriminant $\Delta(k) = 2^{12}3^4$, a square, so the Galois group $G$ of $k$ is a subgroup of $A_4$, by Proposition 9.1. As $4||G|$, $|G| = 4$ or $|G| = 12$. Now we use Dedekind’s Theorem. Factorizing $k$ modulo 5, we find

$$k(X) = (1 + X)(2 + X + 4X^2 + X^3),$$  

hence the Galois group of $k$ has a permutation of the form $(1, 3)$, i.e., an element of order 3. This means that $3||G|$ and it follows that $|G| = 12$. Thus the Galois group of $k$ is isomorphic to $A_4$.

It is also the case that, for $n = 5$, $n = 6$ and $n = 7$, all transitive subgroups of $S_n$ are isomorphic to the Galois group of an irreducible polynomial in $\mathbb{Q}[X]$ (see [22]); however, for $n > 7$, the question is open.
9.4 Reducible polynomials

In the previous section we were concerned with irreducible polynomials. Here we aim to consider reducible polynomials, in particular, products of two polynomials whose Galois groups are known. We will begin with some examples.

Example 1 Let $f(X) = (1 + X^2)(-2 + X^2) \in \mathbb{Q}[X]$. The splitting field of $g(X) = 1 + X^2$ in $\mathbb{C}$ is $\mathbb{Q}(i)$. As $\mathbb{Q}(i)$ is a Galois extension of $\mathbb{Q}$, we have

$$|\text{Gal}(\mathbb{Q}(i)/\mathbb{Q})| = |\mathbb{Q}(i) : \mathbb{Q}| = 2$$

and it follows that the Galois group of $g$ is isomorphic to the cyclic group $C_2$. A similar argument shows that the Galois group of $h(X) = -2 + X^2$ is also isomorphic to $C_2$. We now consider the Galois group of $f$. The splitting field of $f$ in $\mathbb{C}$ is $\mathbb{Q}(i, \sqrt{2})$ and

$$|\mathbb{Q}(i, \sqrt{2}) : \mathbb{Q}| = |\mathbb{Q}(i, \sqrt{2}) : \mathbb{Q}(\sqrt{2})||\mathbb{Q}(\sqrt{2}) : \mathbb{Q}| = 2 \cdot 2 = 4.$$

Using Corollary 7.1, we see that the cardinal of the Galois group $G$ of $f$ is 4, which implies that $G$ is isomorphic to $C_4$ or $C_2 \times C_2$. If $\sigma \in G$, then

$$\sigma(i)^2 = \sigma(-1) = -1 \implies \sigma(i) = \pm i.$$

In the same way

$$\sigma(\sqrt{2})^2 = \sigma(\sqrt{2}) = 2 \implies \sigma(\sqrt{2}) = \pm \sqrt{2}.$$

Hence $\sigma^2(i) = i$ and $\sigma^2(\sqrt{2}) = \sqrt{2}$ and it follows that $\sigma^2 = \text{id}_G$. This means that all elements of $G$ have order 1 or 2 and so $G$ is isomorphic to $C_2 \times C_2$.

Example 2 We consider the polynomial $f(X) = (1 + X + X^2)(3 + X^2) \in \mathbb{Q}[X]$. The splitting field of $g(X) = 1 + X + X^2$ is $\mathbb{Q}(j)$, where $j = \exp(\frac{2\pi i}{3})$. Hence $\mathbb{Q}(j)$ is a Galois extension of $\mathbb{Q}$. It follows that the cardinal of the Galois group of $g$ is 2 and so this group is isomorphic to $C_2$. There is no difficulty in seeing that the Galois group of $h(X) = 3 + X^2$ is also $C_2$. What can we say about the Galois group of $f$? First, the splitting field of $f$ is $\mathbb{Q}(j, i\sqrt{3})$. However, $j = \frac{-1 + i\sqrt{3}}{2}$, and so $\mathbb{Q}(j, i\sqrt{3}) = \mathbb{Q}(j) = \mathbb{Q}(\sqrt{3})$, therefore the Galois group of $f$ is isomorphic to $C_2$.

Example 3 This time we take the polynomial $f(X) = (-2 + X^3)(-5 + X^3) \in \mathbb{Q}[X]$. From Theorem 9.1, the Galois groups of $g(X) = -2 + X^3$ and $h(X) = -5 + X^3$ are both isomorphic to $S_3$. The splitting field of $f$ is

$$\mathbb{Q}(\sqrt[3]{2}, j\sqrt[3]{2}, j^2\sqrt[3]{2}, \sqrt[3]{5}, j\sqrt[3]{5}, j^2\sqrt[3]{5}) = \mathbb{Q}(\sqrt[3]{2}, j\sqrt[3]{2}, \sqrt[3]{5}, j\sqrt[3]{5}) = \mathbb{Q}(\sqrt[3]{2}, j, \sqrt[3]{5}).$$

Clearly $|\mathbb{Q}(\sqrt[3]{2}, j, \sqrt[3]{5}) : \mathbb{Q}| \leq 27$ so the Galois group of $f$ cannot be isomorphic to $S_3 \times S_3$.

In the first example the Galois group of the product of the two polynomials is the product of their Galois groups. In the second and third examples this is not the case. The essential difference is that in the first example the intersection of the splitting fields is $\mathbb{Q}$, while in the other two examples, this is not the case. In the next result we formalize this. (Beforehand it may be useful to briefly look at Appendix A, where semidirect and direct products are handled.)
Theorem 9.3 Let $f \in F[X]$ be separable. Suppose that $f = gh$, with $g, h \in F[X]$ irreducible, $E$ is a splitting field of $f$ and $K$ (resp. $L$) a splitting field of $g$ (resp. $h$) in $E$. Then
\[ \text{Gal}(E/F) \simeq \text{Gal}(K/F) \times \text{Gal}(L/F) \]
if and only if $K \cap L = F$.

Proof First it should be noticed that the separability of $f$, together with Theorem 3.8, ensures that $E$ is a separable extension of $F$. Let us write $G = \text{Gal}(E/F)$, $G_K = \text{Gal}(E/K)$ and $G_L = \text{Gal}(E/L)$. The extensions $K$ and $L$ are normal, so the Galois groups $G_K$ and $G_L$ are normal subgroups of $G$.

As $K$ and $L$ are included in $E$, $KL$ is included in $E$. On the other hand, if $\alpha$ is a root of $f$, then $\alpha$ is a root of $g$ or $h$ and so $f$ splits over $KL$, hence $E \subset KL$. We have shown that $E = KL$. Using Corollary 6.1, we may write
\[ [E : F] = [KL : F] = \frac{[K : F][L : F]}{[K \cap L : F]} \]
If we now suppose that the Galois group of $f$ is the direct product of the Galois groups of $g$ and $h$, then
\[ [E : F] = [K : F][L : F] \implies [K \cap L : F] = 1 \implies K \cap L = F. \]

We now consider the converse. Setting $\tilde{G}$ for the subgroup of $G$ generated by $G_K$ and $G_L$, we have, from Theorem 6.9,
\[ \mathcal{F}(\tilde{G}) = K \cap L = F \implies \tilde{G} = G. \]
From Theorem 6.9 we know that $\mathcal{F}(G_K \cap G_L) = KL = E$. This implies that $G_K \cap G_L = \text{id}_E$. Since $G_K$ and $G_L$ are normal subgroups of $G$, the elements of $G_K$ commute with those of $G_L$ and it follows that $G = \tilde{G} = G_K G_L$. Thus $G = G_K \times G_L$ and it follows that $G_K$ (resp. $G_L$) is isomorphic to $G/G_L$ (resp. $G/G_K$). We have shown that
\[ G \simeq G/G_L \times G/G_K \simeq \text{Gal}(L/F) \times \text{Gal}(K/F), \]
from Theorem 6.6. This ends the proof.

Remark This result may be easily extended to the case where $f$ is a product of more than two polynomials.
Chapter 10

Norm, trace and discriminant

In this chapter we introduce some important notions which will be used later on in the text, in particular, when we come to study in more detail number fields.

10.1 Norm and trace

Let $E$ be a finite extension of a field $F$. For $x \in E$, we define a linear endomorphism $m_x$ of $E$ by

$$m_x(y) = xy,$$

for all $y \in E$. We define the norm and the trace of $x$, relative to the extension $E$ of $F$, by

$$N_{E/F}(x) = \det m_x \quad \text{and} \quad T_{E/F}(x) = \text{tr} m_x.$$ 

We also define the characteristic polynomial of $x$. This is just the characteristic polynomial of the endomorphism $m_x$ and we write $\text{char}_{E/F}(x)$ for this polynomial. To simplify the notation, if $n = [E : F]$, then,

$$\text{char}_{E/F}(x) = (-1)^n N(x) + \cdots - T(x) X^{n-1} + X^n.$$ 

As the coefficients of a matrix of $m_x$ belong to $F$, the coefficients of $\text{char}_{E/F}(x)$ belong to $F$. In particular, if $E$ is a number field and $x \in K$, then $N_{E/Q}(x)$ and $T_{E/Q}(x)$ are rational numbers.

Example Let $n$ be a squarefree integer and $E = \mathbb{Q}(\sqrt{n})$. Then $[K : \mathbb{Q}] = 2$ and $(1, \sqrt{n})$ is a basis of $E$ over $\mathbb{Q}$. If $x = a + b\sqrt{n}$, then

$$m_x(1) = a + b\sqrt{n} \quad \text{and} \quad m_x(\sqrt{n}) = a\sqrt{n} + bn,$$

therefore the matrix of $m_x$ in the basis $(1, \sqrt{n})$ is

$$M = \begin{pmatrix} a & bn \\ b & a \end{pmatrix}.$$ 

Hence

$$N_{E/Q}(x) = a^2 - b^2n \quad \text{and} \quad T_{E/Q}(x) = 2a.$$
If $n$ is negative and $a, b \in \mathbb{Z}$, then $N_{E/Q}(x) \in \mathbb{N}$ and $T_{E/Q}(x) \in \mathbb{N}$.

If $x \in F$, then the matrix of $m_x$ in any basis is just $xI_n$ and so

$$N(x) = x^n, \quad T(x) = nx \quad \text{and} \quad \text{char}(x) = (-x + X)^n.$$  

**Exercise 10.1** Show that the norm is multiplicative, i.e.,

$$N(x_1x_2) = N(x_1)N(x_2),$$

for all $x_1, x_2 \in E$, and that the trace is $F$-linear. Also, show that the mapping

$$B : E \times E \rightarrow F : (x_1, x_2) \mapsto T(x_1x_2)$$

is bilinear.

If $x \in F$, then $m(x, F) = -x + X$, so $\text{char}(x) = m(x, F)^n$. In the next proposition we generalize this fact.

**Proposition 10.1** If $r = [E : F(x)]$, then

$$\text{char}_{E/F}(x) = m(x, F)^r.$$  

**Proof.** First let us consider the case $r = 1$. Then $E = F(x)$. From the Cayley-Hamilton Theorem, we know that $\text{char}(m_x) = 0$, hence

$$(-1)^nN(x)y + \cdots - T(x)x^{n-1}y + x^ny = 0,$$

for all $y \in E$. If we set $y = 1$, then we see that $x$ is a root of $\text{char}(x)$. Hence $m(x, f)|\text{char}(x)$.

Now,

$$n = [E : F] = [F(x) : F] = \deg m(x, F)$$

and so $m(x, F) = \text{char}(x)$, hence the result for $r = 1$.

Now let us consider the general case. Let $y_1, \ldots, y_s$ be a basis of $F(x)$ over $F$ and $z_1, \ldots, z_r$ a basis of $E$ over $F(x)$. The elements $y_iz_j$, with $1 \leq i \leq s$ and $1 \leq j \leq r$, form a basis of $E$ over $F$. Let $A = (a_{kl})$ be the matrix representing $m_x$, in the basis $(y_i)$, for the extension $F(x)$ of $F$. (Notice that $A \in M_s(F)$.) Then

$$xy_i = \sum_{k=1}^s a_{ki}y_k \Rightarrow x(y_iz_j) = \sum_{k=1}^s a_{ki}(y_iz_j).$$

Now we order the basis $(y_iz_j)$ as follows:

$$y_1z_1, y_2z_1, \ldots, y_sz_1, y_1z_2, \ldots, y_sz_2, \ldots, y_1z_r.$$

The matrix representing $m_x$, in the basis $(y_iz_j)$, for the extension $E$ of $F$ is

$$B = \text{diag}(A, \ldots, A).$$

(There are $r$ blocks $A$.) Thus

$$\text{char}_{E/F}(x) = (\det(-A + XI_n))^r = m(x, F)^r,$$

where we have used the case $r = 1$ in the second equality. \square

The following result provides an expression for $N_{E/F}(x)$ in terms of the conjugates of $x$ over $F$.  

91
Corollary 10.1 Let $E$ be a splitting field of the minimal polynomial $m(x, F)$. If $n = [E : F]$, $[F(x) : F] = d$ and $x_1, \ldots, x_d$ are the roots of $m(x, F)$ in $E$ (with repetition of roots possible), then

$$
N_{E/F}(x) = \left( \prod_{i=1}^{d} x_i \right)^{\frac{n}{d}}, \quad T_{E/F}(x) = \frac{n}{d} \sum_{i=1}^{d} x_i
$$

and

$$
\text{char}_{E/F}(x) = \left( \prod_{i=1}^{d} (-x_i + X) \right)^{\frac{n}{d}}.
$$

PROOF We have

$$[E : F] = [E : F(x)][F(x) : F],$$

hence $[E : F(x)] = \frac{n}{d}$. From Proposition 10.1,

$$\text{char}_{E/F}(x) = m(x, F)^\frac{n}{d} = \left( \prod_{i=1}^{d} (-x_i + X) \right)^{\frac{n}{d}}.$$

If

$$m(x, F) = a_0 + a_1 X + \cdots + a_{d-1} X^{d-1} + X^d,$$

then

$$m(x, F)^\frac{n}{d} = a_0^\frac{n}{d} + \cdots + \frac{n}{d} a_{d-1} X^{n-1} + X^n.$$

It is clear that the constant term is $a_0^\frac{n}{d}$; however, the coefficient of $X^{n-1}$ needs an explanation.

From the multinomial theorem, with $a_d = 1$, we have

$$(a_0 + a_1 X + \cdots + a_{d-1} X^{d-1} + X^d)^\frac{n}{d} = \sum_{k_0 + k_1 + \cdots + k_d = \frac{n}{d}} \left( \begin{array}{c} \frac{n}{d} \\ k_0, k_1, \ldots, k_d \end{array} \right) \left( a_i X^i \right)^{k_i}.$$

To obtain the coefficient of $X^{n-1}$, first we notice that

$$k_0 + k_1 + \cdots + k_d = \frac{n}{d} \quad (10.1)$$

and

$$0k_0 + 1k_1 + 2k_2 + \cdots + dk_d = n - 1. \quad (10.2)$$

Multiplying equation (10.1) by $d$ we obtain

$$dk_0 + dk_1 + \cdots + dk_d = n. \quad (10.3)$$

We now subtract equation (10.2) from equation (10.3). This gives us

$$dk_0 + (d - 1)k_1 + (d - 2)k_2 + \cdots + (d - (d - 1)) k_{d-1} = 1,$$

from which we deduce that $k_i = 0$, for $0 \leq i < d - 1$, and $k_{d-1} = 1$. To find $k_d$ it is sufficient to use equation (10.3):

$$d + dk_d = n \implies k_d = \frac{n}{d} - 1.$$

Hence, for the term with $X^{n-1}$ we have

$$\left( \begin{array}{c} \frac{n}{d} \\ 0, \ldots, 0, 1, \frac{n}{d} - 1 \end{array} \right) \left( a_{d-1} X^{d-1} \right)^{1} (X^d)^{\frac{n}{d} - 1} = \frac{n}{d} a_{d-1} X^{n-1}.$$
We may now continue the proof. Since \(a_0 = (-1)^d \prod_{i=1}^d x_i\) and \((-1)^n N(x) = a_0^{\frac{n}{d}}\), we have \(N(x) = \left( \prod_{i=1}^d x_i \right)^{\frac{n}{d}}\). In a similar way, \(a_{d-1} = -\sum_{i=1}^d x_i\) and \(-T(x) = \frac{n}{d} a_{d-1}\) imply that \(T(x) = \frac{2}{3} \sum_{i=1}^d x_i\).

**Separable extensions**

Suppose now that \(E\) is a finite separable extension of the field \(F\). If \([E : F] = n\) and \(C\) is an algebraic closure of \(F\), then there are \(n\) \(F\)-monomorphisms \(\sigma_1, \ldots, \sigma_n\) of \(E\) into \(C\) (Corollary 3.2). (If \(E\) is a number field, then it is natural to take \(C = \mathbb{A}(\mathbb{C}/\mathbb{Q})\), the field of algebraic numbers, from the remark after Theorem 2.6.)

**Proposition 10.2** Suppose that \(E\) is a finite separable extension of \(F\). Then, for all \(x \in E\),

\[
N_{E/F}(x) = \prod_{i=1}^n \sigma_i(x), \quad T_{E/F}(x) = \sum_{i=1}^n \sigma_i(x)
\]

and

\[
\text{char}_{E/F}(x) = \prod_{i=1}^n (-\sigma_i(x) + X).
\]

**Proof** We have

\[
[E : F] = [E : F(x)][F(x) : F].
\]

If \([F(x) : F] = d\), then \([E : F(x)] = \frac{n}{d}\). From Corollary 3.2, we know that there are \(d\) \(F\)-monomorphisms \(\tau_1, \ldots, \tau_d\) of \(F(x)\) into \(C\) and each one of these \(F\)-monomorphisms sends \(x\) to a distinct associate \(x_i\). From Theorem 3.2, each \(\tau_i\) can be extended to an \(F(x)\)-monomorphism \(\sigma_j\) from \(E\) into \(C\). An \(F(x)\)-monomorphism is an \(F\)-monomorphism, thus we obtain \(n = \frac{2}{3} \times d\) \(F\)-monomorphisms \(\sigma_j\) from \(E\) into \(C\). As \([E : F] = n\), these \(F\)-monomorphisms form the complete set of \(F\)-monomorphisms from \(E\) into \(C\). Now we have

\[
\prod_{i=1}^n \sigma_i(x) = \left( \prod_{i=1}^d \tau_i(x) \right)^{\frac{n}{d}} = \left( \prod_{i=1}^d x_i \right)^{\frac{n}{d}} = N_{E/F}(x)
\]

and

\[
\sum_{i=1}^n \sigma_i(x) = \frac{n}{d} \sum_{i=1}^d x_i = \frac{n}{d} \sum_{i=1}^d x_i = T_{E/F}(x).
\]

For the characteristic function we have

\[
\prod_{i=1}^n (-\sigma_i(x) + X) = \left( \prod_{i=1}^d (-\tau_i(x) + X) \right)^{\frac{n}{d}} = \left( \prod_{i=1}^d (-x_i + X) \right)^{\frac{n}{d}} = \text{char}_{E/F}(x).
\]

This finishes the proof. \(\square\)

The proposition which we have just proved has an important corollary. If we have a tower of fields \(F \subset K \subset E\), where \(E\) is a finite extension of \(F\), then it makes sense to speak of the compositions \(N_{K/F} \circ N_{E/K}\) and \(T_{K/F} \circ T_{E/K}\), because \(N_{E/K}(x)\) and \(T_{E/K}(x)\) are elements of \(K\), for any \(x \in E\).
Corollary 10.2 (transitivity of norm and trace) If $K/F$ and $E/K$, where $E$ is a finite separable extension of $F$, then

$$N_{E/F} = N_{K/F} \circ N_{E/K} \quad \text{and} \quad T_{E/F} = T_{K/F} \circ T_{E/K}.$$ 

PROOF Let $n = [K : F]$ and $m = [E : K]$. From Proposition 3.5, $K$ is separable over $F$ and $E$ separable over $K$. Let $N$ be a normal closure of $E$ over $F$. We saw in Section 5.1 that $N$ may be considered as the splitting field of a polynomial $f \in F[X]$ which is a product of minimal polynomials $m(\alpha, F)$, with $\alpha \in E$. As $E$ is a separable extension of $F$, the polynomials $m(\alpha, F)$ are separable, and so $f$ is separable. Therefore, from Corollary 3.4, $N$ is a separable extension of $F$. We have shown that $N$ is a finite Galois extension of $F$.

Let $C$ be an algebraic closure of $N$. From Corollary 3.2, there are $n$ $F$-monomorphisms $\sigma_1, \ldots, \sigma_n$ of $K$ into $C$ and $m$ $K$-monomorphisms from $\tau_1, \ldots, \tau_m$ from $E$ into $C$. Each one of the monomorphisms $\sigma_i$ and $\tau_j$ may be extended to a monomorphism $\hat{\sigma}_i$ or $\hat{\tau}_j$ from $N$ into $C$ (Theorem 3.2). Proposition 5.3 ensures that $N$ is normal over $K$, since $N$ is normal over $F$. Applying Proposition 5.2, we see that, for each $i$ and each $j$, $\hat{\sigma}_i(N) = N$ and $\hat{\tau}_j(N) = N$, hence $\hat{\sigma}_i$ and $\hat{\tau}_j$ are automorphisms of $N$, for each $i$ and $j$. Hence we can compose the mappings $\hat{\sigma}_i$ and $\hat{\tau}_j$.

We now use Proposition 10.2. If $x \in E$, then

$$T_{K/F}(T_{E/K}(x)) = \sum_{i=1}^{n} \sigma_i \left( \sum_{j=1}^{m} \tau_j(x) \right) = \sum_{i=1}^{n} \hat{\sigma}_i \left( \sum_{j=1}^{m} \hat{\tau}_j(x) \right) = \sum_{i=1}^{n} \sum_{j=1}^{m} \hat{\sigma}_i \hat{\tau}_j(x).$$

Each mapping $\hat{\sigma}_i \hat{\tau}_j |_E$ is an $F$-monomorphism of $E$ into $C$ and there are $mn$ such mappings. We claim that for distinct pairs $(i, j)$ these mappings are distinct. Suppose that $\hat{\sigma}_i \hat{\tau}_j = \hat{\sigma}_l \hat{\tau}_k$ on $E$. Then, as $K \subset E$, this is also true on $K$. Given that $\hat{\tau}_j|_K = \hat{\tau}_k|_K = \text{id}_K$, and $\hat{\sigma}_i|_K = \sigma_i$ and $\hat{\sigma}_l|_K = \sigma_l$, we have $\sigma_i = \sigma_l$, i.e., $i = l$. Also, $\hat{\sigma}_i = \hat{\sigma}_l$ and $\hat{\sigma}_i$ is a monomorphism, hence $\hat{\tau}_j(x) = \hat{\tau}_k(x)$, and this is so for any $x \in E$. It follows that $\tau_j = \tau_k$, and thus that $j = k$. We have shown that the $F$-monomorphisms $\hat{\sigma}_i \hat{\tau}_j$, restricted to $E$, are distinct and so form the set of $F$-monomorphisms from $E$ into $C$. Hence, using Proposition 10.2 again, we have

$$T_{E/F}(x) = \sum_{i=1}^{n} \sum_{j=1}^{m} \hat{\sigma}_i \hat{\tau}_j(x) = T_{K/F}(T_{E/K}(x)),$$

for all $x \in E$.

For the norm we proceed in an analogous way:

$$N_{E/F}(x) = \prod_{i=1}^{n} \prod_{j=1}^{m} \hat{\sigma}_i \hat{\tau}_j(x) = \prod_{i=1}^{n} \hat{\sigma}_i \left( \prod_{j=1}^{m} \hat{\tau}_j(x) \right) = N_{K/F}(N_{E/K}(x)).$$

This ends the proof. \qed

Remark Corollary 10.1 supposes that $E$ is a splitting field of the minimal polynomial of $x$ over $F$. Using Corollary 10.2 we may show that Corollary 10.1 is true if the field $E$ only contains a splitting field $K$ of the minimal polynomial (providing that $E$ is a separable extension of $F$). Indeed, we have the tower of fields $F \subset K \subset E$ and $N_{E/F}(x) = N_{K/F} \circ N_{E/K}(x)$. As $x \in K$, we have $N_{E/K}(x) = x^{[E:K]}$. Thus

$$N_{E/F}(x) = (N_{K/F}(x))^{[E:K]} = \left( \prod_{i=1}^{d} x_i^{[K/F][E:K]} \right) = \left( \prod_{i=1}^{d} x_i^{[E:F]} \right)^{[E:K]}.$$

94
For the trace the calculation is analogous.

We now suppose that \( E/F \) is not only separable but also normal, i.e., \( E \) is a Galois extension of \( F \).

**Corollary 10.3** If \( E \) is a finite Galois extension of the field \( F \), then for all \( x \in E \)
\[
N_{E/F}(x) = \prod_{\sigma \in \text{Gal}(E/F)} \sigma(x) \quad \text{and} \quad T_{E/F}(x) = \sum_{\sigma \in \text{Gal}(E/F)} \sigma(x).
\]

**Proof** As \( E \) is a finite separable extension \( F \), there are \( n = [E : F] \) \( F \)-monomorphisms \( \sigma_1, \ldots, \sigma_n \) of \( E \) into an algebraic closure \( C \) of \( F \). However, \( E \) is a normal extension of \( F \) and \( C \) an algebraic closure of \( F \), with \( C/E \), therefore \( \sigma_i(E) = E \) for \( i = 1, \ldots, n \) (Proposition 5.2) and so \( \sigma_1, \ldots, \sigma_n \in \text{Gal}(E/F) \). As the cardinality of \( \text{Gal}(E/F) \) is \( n \), the \( \sigma_i \) form the Galois group. The result now follows from Proposition 10.2.

We conclude this section with a result concerning the bilinear form \( B \) defined in Exercise 10.1:
\[
B : E \times E \to F : (x_1, x_2) \mapsto T_{E/F}(x_1 x_2).
\]

**Corollary 10.4** If \( E \) is a finite separable extension of \( F \), then the bilinear form \( B \) is nondegenerate.

**Proof** Suppose that \( B \) is degenerate, then there exists a nonzero \( x_1 \in E \) such that \( T(x_1 x_2) = 0 \), for all \( x_2 \in E \). If \( x \in E \), then there exists \( x_2 \in E \) such that \( x_1 x_2 = x \), so \( T(x) = 0 \), for all \( x \in E \). However, this means that \( \sum_{i=1}^{n} \sigma_i(x) = 0 \), for all \( x \in E \), which contradicts Dedekind’s lemma (Theorem 8.1). Therefore \( B \) is nondegenerate.

### 10.2 Discriminant of a polynomial

In Section 8.5 we introduced the discriminant of a polynomial. Also, we defined the resultant of two polynomials and stated an important relation between these two concepts. Our aim in this section is to study these concepts in more detail. In order to make the reading easier, we regive the definitions.

#### Resultants

We fix \( m, n \in \mathbb{N}^* \). Let \( F \) be a field, \( f \in F_m[X] \), with coefficients \( a_0, \ldots, a_m \) and \( g \in F_n[X] \), with coefficients \( b_0, \ldots, b_n \). We define the square \( n + m \) **Sylvester matrix** \( S_{m,n}(f,g) \) (or \( S(f,g) \)), if \( m \) and \( n \) are understood) as follows:
\[
S_{m,n}(f,g) = \begin{bmatrix}
am_m & a_{m-1} & a_{m-2} & \cdots & 0 & 0 & 0 \\
a_0 & a_m & a_{m-1} & \cdots & 0 & 0 & 0 \\
\vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots \\
0 & 0 & 0 & \cdots & a_1 & a_0 & 0 \\
0 & 0 & 0 & \cdots & a_2 & a_1 & a_0 \\
b_n & b_{n-1} & b_{n-2} & \cdots & 0 & 0 & 0 \\
0 & b_n & b_{n-1} & \cdots & 0 & 0 & 0 \\
\vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots \\
0 & 0 & 0 & \cdots & b_2 & b_1 & b_0 \\
0 & 0 & 0 & \cdots & b_2 & b_1 & b_0
\end{bmatrix}
\]
We obtain \( S_{m,n}(f,g) \) by shifting the line vector of the coefficients of \( f \) successively to the right by 0, 1, \ldots, \( n - 1 \) steps and the vector line of the coefficients of \( g \) successively to the right by 0, 1, \ldots, \( m - 1 \) steps and then filling in the remaining places with 0.

**Remark** If \( 0 \leq \deg f = k < m \), then we have \( a_m = a_{m-1} = \cdots = a_{k+1} = 0 \) and if \( f = 0 \), then \( a_i = 0 \), for all \( i \). We have an analogous situation if \( \deg g \neq n \).

Here is an example. With \( m = 3 \) an \( n = 2 \), we have

\[
S_{m,n}(f,g) = \begin{pmatrix}
a_3 & a_2 & a_1 & a_0 & 0 \\
0 & a_3 & a_2 & a_1 & a_0 \\
b_2 & b_1 & b_0 & 0 & 0 \\
0 & b_2 & b_1 & b_0 & 0 \\
0 & 0 & b_2 & b_1 & b_0
\end{pmatrix}
\]

The resultant of \( f \) and \( g \), which we note \( R_{m,n}(f,g) \), (or \( R(f,g) \), if \( m \) and \( n \) are understood) is the determinant \( |S_{m,n}(f,g)| \). Clearly,

\[
R_{m,n}(g,f) = (-1)^{mn} R_{m,n}(f,g). \quad (10.4)
\]

**Remark** We may consider the \( a_i \) and \( b_j \) as variables. In this way we obtain a mapping from \( F^{m+1} \times F^{n+1} \) into \( F \), which is \( mn \)-homogeneous.

**Proposition 10.3** Let \( f \in F_m[X] \) et \( g \in F_n[X] \). If \( m \geq n \) and \( h \in F_{m-n}[X] \), then

\[
R(f + hg, g) = R(f,g).
\]

In the same way, if \( m \leq n \) and \( h \in F_{n-m}[X] \), then

\[
R(f, g + hf) = R(f,g).
\]

**Proof** Let us begin with the case \( m \geq n \). If \( h(X) = c \) is a constant polynomial, then the coefficients of \( f + hg \) are

\[
a_m, a_{m-1}, \ldots, a_n + cb_n, a_{n-1} + cb_{n-1}, \ldots, a_0 + cb_0, 0, \ldots, 0.
\]

From this, we see that the first line of \( S(f + hg, g) \) is the first line of \( S(f,g) \) plus \( c \) multiplied by a line in the bloc of the \( b_j \). This also applies to the lines 2, \ldots, \( n \), so in this case we have \( R(f + hg, g) = R(f,g) \).

Now suppose that \( h = cX \). Then the coefficients of \( f + hg \) are

\[
a_m, a_{m-1}, \ldots, a_n + cb_n, a_{n-1} + cb_{n-1}, \ldots, a_1 + cb_0, a_0, 0, \ldots, 0.
\]

Again the first line \( S(f + hg, g) \) is the first line of \( S(f,g) \) plus \( c \) multiplied by a line in the bloc of the \( b_j \). This also applies to the lines 2, \ldots, \( n \), so in this case too we have \( R(f + hg, g) = R(f,g) \).

If \( h = c_0 + c_1 X \), then

\[
R(f + hg, g) = R((f + (c_0 + c_1 X)g, g) = R((f + c_0 g) + c_1 X g, g) = R(f + c_0 g, g) = R(f,g).
\]

Continuing in the same way, we obtain the first result. The second result is obtained in an analogous way.

In the next proposition we consider the case where \( \deg g < n \) or \( \deg f < m \). This result is useful in proving the fundamental theorem which follows.
Proposition 10.4 Let \( f \in F_m[X] \) and \( g \in F_n[X] \). If \( 0 \leq \deg g = k \leq m = \deg f \), then
\[
R_{m,n}(f,g) = a_m^{n-k} R_{m,k}(f,g).
\] (10.5)

If, on the other hand, \( 0 \leq \deg f = k \leq n = \deg g \), then
\[
R_{m,n}(f,g) = (-1)^{(m-k)n} b_n^{m-k} R_{k,n}(f,g).
\] (10.6)

Proof Let us look at the first equation. If \( k = n \), then there is nothing to prove, so let us suppose that \( k < n \). Then \( b_n = 0 \) and the only nonzero element in the first column of the matrix \( S_{m,n}(f,g) \) is \( a_{n-m} \). The submatrix obtained by eliminating the first line and the first column \( S_{m,n}(f,g) \) is \( S_{m,n} - 1 \). If we continue the process, then we finally obtain the first formula.

Now we look at the second formula. Using the formulas (10.4) and (10.5) we have
\[
R_{m,n}(f,g) = (-1)^{m} R_{m,n}(g,f) = (-1)^{m} b_m^{m-k} R_{n,k}(g,f) = (-1)^{m} b_n^{m-k} (-1)^{nk} R_{k,n}(f,g) = (-1)^{(m-k)n} b_n^{m-k} R_{k,n}(f,g).
\]

This ends the proof.

We now turn to one of the most important results of this section. We will see that there is a relation between the roots of the polynomials \( f \) and \( g \) in a splitting field and the resultant.

Theorem 10.1 Let \( f \in F_m[X] \) and \( g \in F_n[X] \). If \( \deg f = m \), then
\[
R_{m,n}(f,g) = a_m^{m} \prod_{i=1}^{m} g(\xi_i),
\]
where the \( \xi_i \) are the roots of \( f \) in some splitting field of \( f \). On the other hand, if \( \deg g = n \), then
\[
R_{m,n}(f,g) = (-1)^{m} b_n^{n} \prod_{j=1}^{n} f(\eta_j),
\]
where the \( \eta_i \) are the roots of \( g \) in some splitting field of \( g \).

Proof We begin with the first formula and suppose that \( n \geq m \) and that \( f \) has the roots \( \xi_1, \ldots, \xi_m \) in some splitting field. We will use an induction on \( s = \deg g \). If \( s = 0 \), then the matrix \( S_{m,n}(f,g) \) is upper triangular and on the diagonal we have \( a_m \) \( n \) times and \( b_0 \) \( m \) times, therefore
\[
R_{m,n}(f,g) = a_m^{m} b_0^{n} = a_m^{m} \prod_{i=1}^{m} g(\xi_i),
\]
so the result is true for \( s = 0 \).

Now suppose that \( 0 < s \leq n \) and the result is true up to \( s - 1 \). Dividing \( g \) by \( f \) we obtain
\[
g = fq + r,
\]
with \( \deg r < \deg f = m \). Then
\[
\deg q = \deg fq - \deg f = \deg(g - r) - m \leq n - m.
\]
From Proposition 10.3 we have
\[ R_{m,n}(f,g) = R_{m,n}(f,g - fg) = R_{m,n}(f,r). \]
We set \( \deg r = k < s \) and use Proposition 10.4 and the induction hypothesis.

**Case 1: \( r \neq 0 \)**

\[
R_{m,n}(f,r) = a_m^{n-k} R_{m,k}(f,r) = a_m^{n-k} a_m^k \prod_{i=1}^m r(\xi_i) = a_m^n \prod_{i=1}^m g(\xi_i),
\]
and so the result is true for \( s \).

**Case 2: \( r = 0 \)**

In this case the last \( m \) lines of the matrix \( S_{m,n}(f,r) \) are composed of zeros, hence \( R_{m,n}(f,r) = 0 \).
In addition, for any root \( \xi_i \) of \( f \), we have \( g(\xi_i) = q(\xi_i)f(\xi_i) = 0 \), which implies that \( \xi_i \) is also a root of \( g \). This implies that the expression \( \prod_{i=1}^m g(\xi_i) \) vanishes, so in this case also we have equality. Thus the result is true for \( s \).

In both cases, the result is true for \( s \), so by induction, the result is true for all \( s \leq n \).

Now let us suppose that \( m > n \). Then \( g \in \mathbb{F}_m[X] \) and, using Proposition 10.4, we have
\[ R_{m,m}(f,g) = a_m^{n-n} R_{m,n}(f,g). \]
In addition, from what we have seen above,
\[ R_{m,m}(f,g) = a_m^m \prod_{i=1}^m g(\xi_i). \]
Therefore,
\[ a_m^{m-n} R_{m,n}(f,g) = a_m^m \prod_{i=1}^m g(\xi_i) \Rightarrow R_{m,n}(f,g) = a_m^n \prod_{i=1}^m g(\xi_i). \]
Hence, for \( m > n \) also the formula holds.

We now consider the second part of the theorem. We suppose that \( g \) has the roots \( \eta_1, \ldots, \eta_n \) in some splitting field. Then,
\[
R_{m,n}(f,g) = (-1)^{mn} R_{n,m}(g,f) = (-1)^{mn} \prod_{j=1}^n f(\eta_j),
\]
where we have used the first part of the theorem.
**Corollary 10.5** If $\deg f = m$, $\deg g = n$ and, in a splitting field of $f$ and $g$, the roots of $f$ (resp. $g$) are $\xi_1, \ldots, \xi_m$ (resp. $\eta_1, \ldots, \eta_n$), then

$$R_{m,n}(f,g) = a_m^m b_n^n \prod_{i=1}^{m} \prod_{j=1}^{n} (\xi_i - \eta_j).$$

**Proof** It is sufficient to notice that

$$g(X) = b_n(X - \eta_1) \cdots (X - \eta_n)$$

and then apply the first part of the theorem. \qed

**Discriminants**

Let $f(X) = \sum_{i=0}^{m} a_i X^i$ a polynomial with coefficients in a field $F$. We suppose that the degree $m$ of $f$ is greater than 1 and that $f$ has the roots $\xi_1, \ldots, \xi_m$ in some splitting field $E$. The **discriminant** of $f$ is defined by

$$\Delta(f) = a_m^{2m-2} \prod_{1 \leq i < j \leq m} (\xi_i - \xi_j)^2.$$

We will see in the theorem which follows that this definition is unambiguous: it does not depend on the splitting field chosen.

It is useful to notice that $\Delta(f)$ belongs to $F$. Indeed, the multivariate polynomial $A = a_m^{2m-2} \prod_{1 \leq i < j \leq m} (X_i - X_j)^2$ is a symmetric polynomial in $F[X_1, \ldots, X_n]$. Consequently, from Corollary B.1, $\Delta(f) \in F$. Using the same corollary, we may also say that, if $f \in R[X]$, where $R$ is an integral domain, then $\Delta(f) \in R$.

In Section 8.5 we stated the following result linking the discriminant of a polynomial and the resultant of the polynomial and its derivative. Here we prove this result.

**Theorem 10.2** If $\text{char } F = 0$ or $\text{char } F = p > 0$ and $p \nmid m$, where $\deg f = m$, then

$$\Delta(f) = (-1)^{m(m-1)/2} a_m^{-1} R_{m,m-1}(f,f').$$

**Proof** We have

$$f(X) = a_m \prod_{i=1}^{m} (X - \xi_i) \implies f'(\xi_i) = a_m \prod_{j \neq i} (\xi_i - \xi_j).$$

Hence,

$$R_{m,m-1}(f,f') = a_m^{m-1} \prod_{i=1}^{m} f'(\xi_i)$$

$$= a_m^{2m-1} \prod_{i=1}^{m} \prod_{j \neq i} (\xi_i - \xi_j)$$

$$= a_m^{2m-1} \prod_{1 \leq i < j \leq m} (\xi_i - \xi_j)(\xi_j - \xi_i)$$

$$= a_m^{2m-1} (-1)^{m(m-1)/2} \prod_{1 \leq i < j \leq m} (\xi_i - \xi_j)^2$$

$$= (-1)^{m(m-1)/2} a_m \Delta(f)$$

99
and the result follows.  

If char $F = p > 0$ and $p|m$, then $\deg f' = k < m - 1$. In this case, if $k \neq -\infty$, then

$$R_{m,m-1}(f, f') = a_m^{m-1-k} R_{m,k}(f, f')$$

and

$$\Delta(f) = (-1)^{m(m-1)/2} a_m^{m-k-2} R_{m,k}(f, f').$$

**Remark** The polynomial $f$ has a multiple root if and only if $\Delta(f) = 0$. From the formulas here, we see that we are able to determine the existence of a multiple root only taking into account the coefficients of $f$. We should also notice that the formulas show that the discriminant belongs to the field $F$.

**Example 1:** $\Delta(b + aX + X^n)$

Our aim in this section is to determine a formula for the discriminant of the polynomial $f(X) = a + bX + X^n \in F[X]$. We will suppose that $E$ is a field containing $F$ and the roots of $f$.

**Lemma 10.1** If $f \in F[X]$ is monic and $\alpha_0 \in E$, then

$$\Delta((-\alpha_0 + X)f(X)) = f(\alpha_0)^2 \Delta(f(X)).$$

**Proof** Let $\alpha_1, \ldots, \alpha_n$ be the roots of $f$ in $E$. Then the roots of $(-\alpha_0 + X)f(X)$ are $\alpha_0, \alpha_1, \ldots, \alpha_n$ and

$$\Delta((-\alpha_0 + X)f(X)) = \prod_{0 \leq i < j \leq n} (\alpha_i - \alpha_j)^2$$

$$= \prod_{1 \leq j \leq n} (\alpha_0 - \alpha_j)^2 \prod_{1 \leq i < j \leq n} (\alpha_i - \alpha_j)^2$$

$$= f(\alpha_0)^2 \Delta(f(X)).$$

This ends the proof.  

We need a second preliminary result.

**Lemma 10.2** If $f(X) = c + X^n \in F[X]$, then

$$\Delta(f) = (-1)^{\frac{n(n-1)}{2}} n^n c^{n-1}.$$  

**Proof** Let $\alpha_1, \ldots, \alpha_n$ be the roots of $f$ in $E$. Then

$$\alpha_1 \cdots \alpha_n = (-1)^n c. \quad (10.7)$$

Also,

$$f(X) = \prod_{i=1}^n (-\alpha_i + X) \implies f'(X) = \sum_{i=1}^n \prod_{j \neq i} (-\alpha_j + X) \implies f'(\alpha_i) = \prod_{j \neq i} (-\alpha_j + \alpha_i).$$

It now follows that

$$(-1)^{\frac{n(n-1)}{2}} \Delta(f) = \prod_{i=1}^n f'(\alpha_i) = \prod_{i=1}^n n\alpha_i^{n-1}$$

100
and, using the identity (10.7), we obtain
\[
(-1)^{\frac{n(n-1)}{2}} \Delta(f) = n^n (\alpha_1 \cdots \alpha_n)^{n-1} = n^n (-1)^{\frac{n(n-1)}{2}} c^{n-1} = n^n c^{n-1},
\]
hence the result.

We are now in a position to consider the polynomial \( f(X) = b + aX + X^n \in F[X] \). The following theorem provides a formula for the discriminant of \( f \) involving only its coefficients.

**Theorem 10.3** For the polynomial \( f(X) = b + aX + X^n \in F[X] \), with \( n \geq 2 \), we have the formula
\[
\Delta(f) = (-1)^{\frac{n(n-1)}{2}} (n-1)^{n-1} a^n + (-1)^{\frac{n(n-1)}{2}} n^n b^{n-1}.
\]

**Proof** For the case where \( a = 0 \) we may use Lemma 10.2, so we may suppose that \( a \neq 0 \). We begin with the case where \( b = 0 \). Then, using Lemmas 10.1 and 10.2, we have
\[
\Delta(f) = \Delta(a + X^{n-1}) = a^2 \Delta(a + X^{n-1}) = a^2 (-1)^{\frac{n(n-1)}{2}} (n-1)^{n-1} a^{n-2} = (-1)^{\frac{n(n-1)}{2}} (n-1)^{n-1} a^n.
\]
because \( b = 0 \).

Now we turn to the case where \( b \neq 0 \). The calculations are much longer. If \( \alpha_1, \ldots, \alpha_n \) are the roots of \( f \), then, for all \( i \),
\[
b + a\alpha_i + \alpha_i^n = 0 \quad \text{and} \quad \alpha_1 \cdots \alpha_n = (-1)^n b. \quad (10.8)
\]
As \( b \neq 0 \), none of the roots \( \alpha_i \) vanish. Now, proceeding as in the proof of Lemma 10.2, and setting \( A = (-1)^{\frac{n(n-1)}{2}} \Delta(f) \), we have
\[
A = \prod_{i=1}^{n} f'(\alpha_i) = \prod_{i=1}^{n} (a + n\alpha_i^{n-1}) = \prod_{i=1}^{n} \frac{a\alpha_i + n\alpha_i^n}{\alpha_i}.
\]
Using the expressions (10.8), we continue:

\[
A = \frac{(-1)^{n}}{b} \prod_{i=1}^{n} (\alpha_{i} + n\alpha_{i}^{n}) = \frac{(-1)^{n}}{b} \prod_{i=1}^{n} (\alpha_{i} + n(-b - \alpha_{i})) = \frac{(-1)^{n}}{b} \prod_{i=1}^{n} (-bn - a(n-1)\alpha_{i})
\]

\[
= \frac{(-1)^{n}}{b} \prod_{i=1}^{n} \left( \frac{-bn}{a(n-1)} - \alpha_{i}a(n-1) \right) = \frac{(-1)^{n}}{b} a^{n}(n-1)^{n} \prod_{i=1}^{n} \left( -\frac{bn}{a(n-1)} - \alpha_{i} \right)
\]

\[
= \frac{(-1)^{n}}{b} a^{n}(n-1)^{n} \left( bn + a(n-1) \right) = \left( -\frac{bn}{a(n-1)} \right)^{n}
\]

We now simplify the expression on the right-hand side:

\[
A = \frac{(-1)^{n}}{b} \left( (-1)^{n}b^{n}a^{n} - a^{n}bn(n-1)^{(n-1)} + a^{n}b(n-1)^{n} \right) = \left( -1 \right)^{n} \left( (-1)^{n}b^{n-1}a^{n} - a^{n}n(n-1)^{n-1} + a^{n}(n-1)^{n} \right)
\]

\[
= b^{-n}n^{n} - (-1)^{n}(n-1)^{n-1}a^{n} = (-1)^{n-1}(n-1)^{n-1}a^{n} + n^{n}b^{n-1} = (-1)^{1-n}(n-1)^{n-1}a^{n} + n^{n}b^{n-1}
\]

Multiplying through by \((-1)^{\frac{n(n-1)}{2}}\), we obtain the desired result. \(\square\)

**Applications** We have

- for \(n = 2\), \(\Delta(f) = a^{2} - 4b\);
- for \(n = 3\), \(\Delta(f) = -4a^{3} - 27b^{2}\);
- for \(n = 4\), \(\Delta(f) = -27a^{4} + 256b^{3}\).

**Example 2: \(\Delta(\Phi_{p})\)**

**Proposition 10.5** If \(p\) is an odd prime, then

\[
\Delta(\Phi_{p}) = (-1)^{\frac{p+1}{2}}p^{p-2}.
\]

**Proof** Let \(\zeta\) be a primitive \(p\)th root of unity. Then

\[ -1 + X^{p} = (-1 + X)\Phi_{p}(X) \implies pX^{p-1} = \Phi_{p}(X) + (-1 + X)\Phi'_{p}(X). \]
Substituting $\zeta^i$ for $X$, since $\Phi_p(\zeta^i) = 0$, we obtain
\[
\prod_{i=1}^{p-1} \Phi'_p(\zeta^i) = \prod_{i=1}^{p-1} \frac{p^{\delta(i)}(-1 + \zeta^i)}{(-1 + \zeta^i)} = \frac{p^{p-1}}{\prod_{i=1}^{p-1} (-1 + \zeta^i)} = \frac{p^{p-1}}{(-1)^{p-1} \Phi_p(1)} = p^{p-2}.
\]
(The second equality follows from the relations $\sum_{i=1}^{p-1} i = \frac{p(p-1)}{2}$ and $\zeta^p = 1$ and the third from the identity $\Phi_p(X) = 1 + X + \cdots + X^{p-1}$.)

Also,
\[
\Phi_p(X) = \prod_{i=1}^{p-1} (-\zeta^i + X) \quad \Rightarrow \quad \Phi'_p(X) = \sum_{i=1}^{p-1} \prod_{j \neq i} (-\zeta^j + X)
\]
\[
\Rightarrow \quad \Phi'_p(\zeta^i) = \prod_{j \neq i} (-\zeta^j + \zeta^i)
\]
\[
\Rightarrow \quad \prod_{i=1}^{p-1} \Phi'_p(\zeta^i) = \prod_{i=1}^{p-1} \prod_{j \neq i} (-\zeta^j + \zeta^i) = \prod_{j \neq i} (-\zeta^j + \zeta^i).
\]

Therefore,
\[
\Delta(\Phi_p) = \prod_{j<i}(\zeta^j - \zeta^i)^2 = (-1)^{\frac{(p-2)(p-1)}{2}} \prod_{j \neq i} (\zeta^j - \zeta^i) = (-1)^{\frac{p-1}{2}} p^{p-2}.
\]

This ends the proof. \square

### 10.3 General discriminants

We have seen the notion of the discriminant of a polynomial. Here we extend this notion, although at first it will not be clear how the new concept is actually an extension of the previous one. This we will see later.

Let $E$ be a finite separable extension of degree $n$ of a field $F$. We note $\sigma_1, \ldots, \sigma_n$ the $n$ $F$-monomorphisms of $E$ into an algebraic closure $C$ of $E$ and we take $n$ elements $\alpha_1, \ldots, \alpha_n$ in $E$. We define the discriminant of the set $\alpha_1, \ldots, \alpha_n$ by
\[
\text{disc}_{E/F}(\alpha_1, \ldots, \alpha_n) = |\sigma_i(\alpha_j)|^2,
\]
i.e., the square of the determinant of the matrix $S = (\sigma_i(\alpha_j))$. As we take the square of the determinant, the order of the $\sigma_i$ and $\alpha_j$ do not have an effect on the value of the discriminant. We will also see that the discriminant does not depend on the algebraic closure we use, hence we are justified in speaking of the discriminant.

**Exercise 10.2** Show that
• \( \text{disc}_{E/F}(x\alpha_1, \ldots, \alpha_n) = x^2 \text{disc}_{E/F}(\alpha_1, \ldots, \alpha_n) \), for any \( x \in F \);

• If \( \beta \) is a linear combination of \( \alpha_2, \ldots, \alpha_n \), with coefficients in \( F \), then
  \( \text{disc}_{E/F}(\alpha_1 + \beta, \alpha_2, \ldots, \alpha_n) = \text{disc}_{E/F}(\alpha_1, \ldots, \alpha_n) \).

The next result is useful as we will see later on.

**Proposition 10.6** Suppose that \( U = \{u_1, \ldots, u_n\} \) and \( V = \{v_1, \ldots, v_n\} \) are sets of vectors in \( E \) such that \( u_i = \sum_{j=1}^n a_{ij} v_j \), with \( a_{ij} \in F \). Then

\[
\text{disc}_{E/F}(u_1, \ldots, u_n) = (\det(a_{ij}))^2 \text{disc}_{E/F}(v_1, \ldots, v_n).
\]

**Proof** By definition

\( \text{disc}_{E/F}(u_1, \ldots, u_n) = (\det(\sigma_i(u_j)))^2 \),

where the \( \sigma_i \) are the \( n \) \( F \)-monomorphisms of \( E \) into an algebraic closure of \( E \). Now

\[
\sigma_i(u_j) = \sigma_i(\sum_{k=1}^n a_{jk} v_k) = \sum_{k=1}^n a_{jk} \sigma_i(v_k).
\]

We define the matrices \( X = (\sigma_i(u_j)) \), \( A = (a_{ij}) \) and \( Y = (\sigma_i(v_j)) \). Then \( X = YA^t \) and so

\[
(\det(X))^2 = (\det(YA^t))^2, \quad \text{i.e.,}
\]

\[
\text{disc}_{E/F}(u_1, \ldots, u_n) = (\det(a_{ij}))^2 \text{disc}_{E/F}(v_1, \ldots, v_n),
\]

as required. \( \square \)

The next result will enable us to show that the discriminant is indeed independant of the algebraic closure of \( E \) chosen.

**Proposition 10.7** We have

\[
\text{disc}_{E/F}(\alpha_1, \ldots, \alpha_n) = |T_{E/F}(\alpha_i\alpha_j)|,
\]

where \( |T_{E/F}(\alpha_i\alpha_j)| \) is the determinant of the matrix \( T = (T_{E/F}(\alpha_i\alpha_j)) \).

**Proof** As above let us set \( S = (\sigma_i(\alpha_j)) \). Then

\[
S^t S = \left( \sum_{k=1}^n \sigma_k(\alpha_i\alpha_j) \right) = (T_{E/F}(\alpha_i\alpha_j)),
\]

hence

\[
|S|^2 = |T_{E/F}(\alpha_i\alpha_j)|.
\]

This ends the proof. \( \square \)

**Remark** From the proposition we see that \( \text{disc}_{E/F}(\alpha_1, \ldots, \alpha_n) \) is independant of the algebraic closure chosen. Also, as \( T_{E/F}(\alpha_i\alpha_j) \in F \), for \( 1 \leq i, j \leq n \), we have \( \text{disc}_{E/F}(\alpha_1, \ldots, \alpha_n) \in F \).

The discriminant can help us to determine whether \( n \) elements in an extension of degree \( n \) form a basis of the extension.
Proposition 10.8 The elements $\alpha_1, \ldots, \alpha_n$ form a basis of $E$ over $F$ if only if their discriminant does not vanish.

Proof Let $\sum_{j=1}^n c_j \sigma_j = 0$, where the $c_j \in F$ and at least one $c_j \neq 0$. Then, for $1 \leq i \leq n$, $\sum_{j=1}^n c_j \sigma_i(\alpha_j) = 0$. This implies that the columns of the matrix $S = (\sigma_i(\alpha_j))$ are dependent. It follows that $\disc_{E/F}(\alpha_1, \ldots, \alpha_n) = 0$.

Now suppose that the $\alpha_i$ are independent and so form a basis of $E$ over $F$. If $\disc_{E/F}(\alpha_1, \ldots, \alpha_n) = 0$, then the rows of the matrix $S$ are dependent, hence there exist elements $c_1, \ldots, c_n \in F$, with at least one $c_j \neq 0$, such that $\sum_{i=1}^n c_i \sigma_i(\alpha_j) = 0$, for $1 \leq j \leq n$. As the $\alpha_j$ form a basis of $E$ over $F$, we have $\sum_{i=1}^n c_i \sigma_i(u) = 0$, for all $u \in E$; therefore the monomorphisms $\sigma_i$ are dependent. However, this contradicts Corollary 8.1. Hence $\disc_{E/F}(\alpha_1, \ldots, \alpha_n) \neq 0$. □

In Section 8.5 we defined the discriminant of a polynomial. There is a relation between this notion and the notion of discriminant which we have defined here.

Proposition 10.9 Let $E$ be a finite separable extension of a field $F$; then there exists $\alpha \in E$ such that $E = F(\alpha)$ (Proposition 3.4). If $m = m(\alpha, F)$ and $\deg m = n$, then the elements $1, \alpha, \ldots, \alpha^{n-1}$ form a basis of $E$ over $F$. We have

$$\disc_{E/F}(1, \alpha, \ldots, \alpha^{n-1}) = \Delta(m) = (-1)^{\frac{n(n-1)}{2}} N_{E/F}(m'(\alpha)).$$

Proof Let $C$ be an algebraic closure of $E$ and $\sigma_1, \ldots, \sigma_n$ the $n$ $F$-monomorphisms from $E$ into $C$. Since $E = F(\alpha)$, each $\sigma_i$ is determined $\sigma_i(\alpha)$. Moreover, $\alpha$ is a root of $m \in F[X]$, so $\sigma_i(\alpha)$ is also a root of $m$. If $\alpha = \alpha_1, \alpha_2, \ldots, \alpha_n$ are the roots of $m$, then we may suppose, without loss of generality, that $\sigma_1(\alpha) = \alpha_1$. Consequently, $\sigma_i(\alpha^j) = \alpha_i^j$ and $\disc_{E/F}(1, \alpha, \ldots, \alpha^{n-1})$ is the square of the determinant of the matrix

$$S = \begin{pmatrix} 1 & \alpha_1 & \alpha_1^2 & \cdots & \alpha_1^{n-1} \\ 1 & \alpha_2 & \alpha_2^2 & \cdots & \alpha_2^{n-1} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & \alpha_n & \alpha_n^2 & \cdots & \alpha_n^{n-1} \end{pmatrix}.$$

However, $S$ is a Vandermonde matrix, therefore

$$|S|^2 = \prod_{i<j}(\alpha_i - \alpha_j)^2 = \Delta(m).$$

Moreover,

$$\prod_{i<j}(\alpha_i - \alpha_j)^2 = (-1)^{\frac{n(n-1)}{2}} \prod_{i \neq j}(\alpha_i - \alpha_j)$$

and, from Proposition 10.2,

$$N_{E/F}(m'(\alpha)) = \prod_{i=1}^n \sigma_i(m'(\alpha)).$$

Now, $\sigma_i(m'(\alpha)) = m'(\sigma_i(\alpha))$, because $m \in F[X]$, thus

$$N_{E/F}(m'(\alpha)) = \prod_{i=1}^n m'(\sigma_i(\alpha)) = \prod_{i=1}^n m'(\alpha_i).$$
Finally, as \( m(X) = \prod_{i=1}^{n} (-\alpha_i + X) \), we have
\[
m'(\alpha_i) = \prod_{j \neq i} (-\alpha_j + \alpha_i)
\]
and so
\[
N_{E/F}(m'(\alpha)) = \prod_{i=1}^{n} \prod_{j \neq i} (-\alpha_j + \alpha_i)
= \prod_{j \neq i} (-\alpha_j + \alpha_i)
= (-1)^{\frac{n(n-1)}{2}} \prod_{i<j} (\alpha_i - \alpha_j)^2,
\]
which implies that
\[
\Delta(m) = (-1)^{\frac{n(n-1)}{2}} N_{E/F}(m'(\alpha)).
\]
This ends the proof.

**Remark** From Proposition 10.9 and the calculation of the discriminant of the \( p \)-th cyclotomic polynomial \( \Phi_p \) for \( p \) an odd prime (Proposition 10.5), we obtain
\[
\text{disc}_{\mathbb{Q}(\zeta)/\mathbb{Q}}(1, \zeta, \ldots, \zeta^{p-2}) = (-1)^{\frac{p-1}{2}} p^{p-2},
\]
where \( \zeta \) is a primitive \( p \)-th root of unity, because \( \Phi_p \) is the minimal polynomial of \( \zeta \) over \( \mathbb{Q} \).

We now use the previous proposition and the notion of norm and trace to calculate the discriminant of the \( p^r \)-th cyclotomic polynomial, where \( r \in \mathbb{N}^* \).

**Corollary 10.6** We have
\[
\Delta(\Phi_{p^r}) = (-1)^c p^{r-1(p-1)-1},
\]
where \( c = \frac{\phi(p^r)}{2} \), if \( p \) is odd or \( r > 1 \), and \( c = 0 \) otherwise. (\( \phi \) is the Euler function.)

**Proof** Let \( \zeta \) be a primitive \( p^r \)-th root of unity. Setting \( n = \phi(p^r) = p^r-1(p-1) \), from Proposition 10.9
\[
\Delta(\Phi_{p^r}) = \text{disc}_{\mathbb{Q}(\zeta)/\mathbb{Q}}(1, \zeta, \ldots, \zeta^{n-1}) = (-1)^{\frac{n(n-1)}{2}} N_{\mathbb{Q}(\zeta)/\mathbb{Q}}(\Phi_{p^r}'(\zeta)).
\]
We now calculate the norm. First, using Exercise 7.4, we have
\[
\Phi_{p^r}'(X) = \Phi_p(X^{p^{r-1}}) = \frac{X^{p^r} - 1}{X^{p^{r-1}} - 1} \implies \Phi_{p^r}'(\zeta) = \frac{p^r \zeta^{p^{r-1}-1} (\zeta^{p^{r-1}} - 1)}{(\zeta^{p^{r-1}} - 1)^2},
\]
because \( \zeta^{p^{r-1}} - 1 = 0 \). Hence,
\[
\Phi_{p^r}'(\zeta) = \frac{p^r \zeta^{p^{r-1}-1}}{\zeta^{p^{r-1}} - 1}.
\]
To calculate \( N_{\mathbb{Q}(\zeta)/\mathbb{Q}}(\Phi_{p^r}'(\zeta)) \) we use the multiplicity of the norm. To begin, we determine \( N_{\mathbb{Q}(\zeta)/\mathbb{Q}}(\zeta^{p^{r-1}}) \). This norm is the product of all the primitive \( p^r \)-th roots of unity (Corollary
Hence, we have to consider \(10.1\), i.e., \((-1)^n\) times the constant term of \(\Phi_p\). However, \(\Phi_p(X) = \Phi_p(X^{p^{-1}})\) (Exercise 7.4) and \(\Phi_p(X) = 1 + \cdots + X^{p-1}\), hence

\[
N_{\mathbb{Q}(\zeta)/\mathbb{Q}}(\zeta^{p^{-1}} - 1) = (-1)^n.
\]

Let us now calculate \(N_{\mathbb{Q}(\zeta)/\mathbb{Q}}(\zeta^{p^{-1}} - 1)\). To do so we initially notice that \(\zeta^{p^{-1}}\) is a primitive \(p\)th root of unity. \((\zeta^{p^{-1}})\) is clearly a \(p\)th root of unity; if \((\zeta^{p^{-1}})^k = 1\), with \(k < p\), then there is a power \(u\) of \(\zeta\) less that \(p^{\nu}\) such that \(p^u = 1\), which is impossible, so \(\zeta^{p^{-1}}\) is a primitive \(p\)th root of unity.) Let \(\xi\) be a primitive \(p\)th root of unity. We apply Corollary 10.3 to the tower of fields \(\mathbb{Q} \subset \mathbb{Q}(\xi) \subset \mathbb{Q}(\zeta)\) to obtain

\[
N_{\mathbb{Q}(\zeta)/\mathbb{Q}}(\zeta^{p^{-1}} - 1) = N_{\mathbb{Q}(\zeta)/\mathbb{Q}} \circ N_{\mathbb{Q}(\xi)/\mathbb{Q}}(\zeta^{p^{-1}} - 1).
\]

Moreover,

\[
N_{\mathbb{Q}(\zeta)/\mathbb{Q}}(\zeta^{p^{-1}} - 1) = (\zeta^{p^{-1}} - 1)^{p^{-1}},
\]

since \(\zeta^{p^{-1}} - 1 \in \mathbb{Q}(\xi)\) and

\[
\left[\mathbb{Q}(\zeta) : \mathbb{Q}(\xi)\right] = \left[\mathbb{Q}(\xi) : \mathbb{Q}\right] \cdot \frac{\phi(p)}{\phi(p^{\nu})} = p^{\nu-1}.
\]

Hence, we have to consider

\[
N_{\mathbb{Q}(\zeta)/\mathbb{Q}}(\zeta^{p^{-1}} - 1) = (N_{\mathbb{Q}(\zeta)/\mathbb{Q}}(\zeta^{p^{-1}} - 1))^{p^{-1}}.
\]

Since \(\zeta^{p^{-1}}\) is a primitive \(p\)th root of unity, its minimal polynomial over \(\mathbb{Q}\) is \(\Phi_p\). The minimal polynomial of \(\zeta^{p^{-1}} - 1\) over \(\mathbb{Q}\) is \(\Phi_p(1 - X)\), which has the splitting field \(\mathbb{Q}(\zeta)\). Therefore, from Corollary 10.1,

\[
N_{\mathbb{Q}(\xi)/\mathbb{Q}}(\zeta^{p^{-1}} - 1) = \prod_{i=1}^{p^{-1}} (\zeta^{p^{-1}} - 1) = (-1)^{p^{-1}} \Phi_p(1) = (-1)^{p^{-1}} p
\]

and

\[
N_{\mathbb{Q}(\zeta)/\mathbb{Q}}(\zeta^{p^{-1}} - 1) = (-1)^{p^{-1} (p-1)} p^{p-1}.
\]

To conclude

\[
N_{\mathbb{Q}(\zeta)/\mathbb{Q}}(\Phi_p(\zeta)) = \frac{\Phi_p^n(n_{\mathbb{Q}(\zeta)/\mathbb{Q}}(\zeta^{p^{-1}} - 1))}{N_{\mathbb{Q}(\zeta)/\mathbb{Q}}(\zeta^{p^{-1}} - 1)} = \frac{\Phi_p^n(-1)^n}{(-1)^n p^{p^{-1}}} = p^{n-1} (r(p-1)-1).
\]

If \(p\) is odd or \(r > 1\), then \(n = \phi(p^{\nu})\) is even and the parity of \(\frac{n(n-1)}{2}\) is that of \(\frac{n}{2}\). On the other hand, if \(p\) is even and \(r = 1\), then \(n = \phi(2) = 1\), so \((-1)^{n(n-1)/(2)} = 1\). This finishes the proof. \(\square\)

Further on we will generalize this result, i.e., we will determine \(\Delta(\Phi_n)\), for any \(n \in \mathbb{N}^+\).
Part II

Algebraic Number Theory
Chapter 11

Number fields

In our previous work we have already seen number fields, namely finite extensions of the rational numbers \( \mathbb{Q} \). In this chapter we will look into these fields in more detail. In particular, we will study a natural subring occurring in such fields, namely that composed of algebraic integers.

11.1 Algebraic integers

We recall that an algebraic number is an element \( \alpha \in \mathbb{C} \) for which there is a polynomial \( f \in \mathbb{Z}[X] \), such that \( f(\alpha) = 0 \). The algebraic numbers form an extension of the field \( \mathbb{Q} \). We say that \( \alpha \in \mathbb{C} \) is an algebraic integer if there is a monic polynomial \( f \in \mathbb{Z}[X] \), such that \( f(\alpha) = 0 \). An algebraic integer is an algebraic number, but the converse is not necessarily true; for example, as we will soon see, a rational number is an algebraic integer only if it is an integer.

Lemma 11.1 Let \( f \in \mathbb{Z}[X] \) and \( f = gh \), with \( g, h \in \mathbb{Q}[X] \). If \( f \) and \( g \) are monic, then \( g, h \in \mathbb{Z}[X] \).

Proof Let \( m \) (resp. \( n \)) be the smallest positive integer such that \( mg \) (resp. \( nh \)) belongs to \( \mathbb{Z}[X] \). (We recall that the content of a polynomial in \( \mathbb{Z}[X] \) is the hcf of its coefficients.) If \( c(mg) \neq 1 \), then the coefficients of \( mg \) have a common divisor \( d > 1 \), such that \( d|m \), since \( g \) is monic. If we set \( m' = \frac{m}{d} \), \( d < m \), then \( m'g \in \mathbb{Z}[X] \), a contradiction, since \( m' \) is a positive integer. A similar argument applies to \( c(nh) \). We claim that this in turn implies that \( m = n = 1 \): If \( m > 1 \) or \( n > 1 \), then \( mn > 1 \); for \( p \) a prime divisor of \( mn \), we have

\[
mnf = (mg)(nh) \implies \bar{0} = \bar{m}g\bar{h},
\]

where the bars indicate the reductions modulo \( p \). As \( \mathbb{Z}_p[X] \) is an integral domain, because \( \mathbb{Z}_p \) is a field, \( m\bar{g} = 0 \) or \( \bar{n}h = 0 \), which implies that \( p \) divides the coefficients of \( mg \) or the coefficients of \( nh \). However, this is impossible, because \( c(mg) = c(nh) = 1 \). Therefore \( m = n = 1 \), as claimed. This implies that \( g, h \in \mathbb{Z}[X] \). \( \square \)

Theorem 11.1 If \( \alpha \in \mathbb{C} \) is an algebraic integer, then there is a monic polynomial \( f \in \mathbb{Z}[X] \) such that \( f(\alpha) = 0 \). If \( f \) is of minimal degree, then \( f \) is irreducible in \( \mathbb{Q}[X] \).

Proof If \( f \) is reducible in \( \mathbb{Q}[X] \), then there are nonconstant polynomials \( g, h \in \mathbb{Q}[X] \) such that \( f = gh \). We may suppose that \( g \) and \( h \) are monic. From Lemma 11.1, we have \( g, h \in \mathbb{Z}[X] \). In
addition, \( g(\alpha) = 0 \) or \( h(\alpha) = 0 \). However, \( \deg g < \deg f \) and \( \deg h < \deg f \) and so we have a contradiction to the minimality of \( f \). Thus \( f \) is irreducible.

From this result we obtain an important corollary.

**Corollary 11.1** If \( \alpha \in \mathbb{C} \) is an algebraic integer, then the polynomial \( m = m(\alpha, \mathbb{Q}) \) lies in \( \mathbb{Z}[X] \).

**Proof** Let \( f \) be a monic polynomial in \( \mathbb{Z}[X] \) of minimal degree such that \( f(\alpha) = 0 \). Then \( f \) is irreducible in \( \mathbb{Q}[X] \) and \( m|f \). It follows that \( m = f \).

**Exercise 11.1** Show that if \( E \) is a number field and \( x \in E \) is an algebraic integer, then \( N_{E/\mathbb{Q}}(x) \) and \( T_{E/\mathbb{Q}}(x) \) are integers.

We now consider the algebraic integers in \( \mathbb{Q} \).

**Theorem 11.2** The number \( \alpha \in \mathbb{Q} \) is an algebraic integer if and only if \( \alpha \) is an integer.

**Proof** If \( \alpha \in \mathbb{Z} \), then \( f(X) = -\alpha + X \in \mathbb{Z}[X] \) and \( f \) is monic. Clearly \( f(\alpha) = 0 \), so \( \alpha \) is an algebraic integer. Now suppose that \( \alpha \in \mathbb{Q} \) is algebraic. If \( m = m(\alpha, \mathbb{Q}) \), then \( m \in \mathbb{Z}[X] \) and \( m(\alpha) = 0 \). As \( \alpha \) is a root of \( m \), \( g(X) = -\alpha + X \) divides \( m \). Now, \( m \) is irreducible and so \( g = m \); it follows that \( m \in \mathbb{Z}[X] \), which implies that \( \alpha \in \mathbb{Z} \).

We will now establish criteria permitting us to decide whether a complex number is an algebraic integer. This will enable us to show that the collection of algebraic integers, which we will note \( \mathcal{O} \), is a subring of the field of algebraic numbers.

**Theorem 11.3** The following conditions are equivalent:

- **a.** \( \alpha \) is an algebraic integer;
- **b.** The additive group of the ring \( \mathbb{Z}[\alpha] \) is finitely generated;
- **c.** \( \alpha \) belongs to a subring \( R \) of \( \mathbb{C} \) whose additive group is finitely generated;
- **d.** There is a finitely generated subgroup \( G \neq \{0\} \) of the additive group of \( \mathbb{C} \) such that \( \alpha G \subset G \).

**Proof**

- **a.** \( \Rightarrow b. \) If \( \alpha \) is a root of a monic polynomial \( f \in \mathbb{Z}[X] \) and \( \deg f = n \), then the additive group of \( \mathbb{Z}[\alpha] \) is generated by the elements \( 1, \alpha, \ldots, \alpha^{n-1} \).
- **b.** \( \Rightarrow c. \) \( \Rightarrow d. \) These implications are elementary.
- **d.** \( \Rightarrow a. \) Suppose that \( a_1, \ldots, a_n \) generate \( G \). Then each term \( \alpha a_i \) can be expressed as a linear combination of the \( a_i \) with coefficients in \( \mathbb{Z} \). Therefore there is a matrix \( M \in \mathcal{M}_n(\mathbb{Z}) \) such that

\[
\begin{pmatrix}
\alpha a_1 \\
\vdots \\
\alpha a_n
\end{pmatrix} = M
\begin{pmatrix}
a_1 \\
\vdots \\
a_n
\end{pmatrix} \implies (\alpha I_n - M)
\begin{pmatrix}
a_1 \\
\vdots \\
a_n
\end{pmatrix} = 0.
\]

As all the \( a_i \) are nonzero, \( \det(\alpha I - M) = 0 \). However, this determinant can be written:

\[
\alpha^n + c_{n-1}\alpha^{n-1} + \cdots + c_1\alpha + c_0 = 0,
\]

with \( c_1 \in \mathbb{Z} \). Hence we have a monic polynomial \( f \in \mathbb{Z}[X] \) such that \( f(\alpha) = 0 \).

We may now show that the subset \( \mathcal{O} \) of \( \mathbb{C} \) composed of algebraic integers is a ring.
Corollary 11.2 The subset $O$ of $C$ is a ring.

Proof It is sufficient to show that $\alpha + \beta$ and $\alpha\beta$ are in $O$, when $\alpha$ and $\beta$ are in $O$. Let $m, n$ be the degrees of the minimal polynomials of $\alpha, \beta$. Then $1, \alpha, \ldots, \alpha^{m-1}$ is a generating set of the additive group of $Z[\alpha]$ and $1, \beta, \ldots, \beta^{n-1}$ a generating set of the additive group of $Z[\beta]$. The elements $\alpha^i\beta^j$, for $0 \leq i \leq m$ and $0 \leq j \leq n$, form a generating set of the additive group of the ring $Z[\alpha, \beta]$. As $Z[\alpha + \beta]$ is a subring of $Z[\alpha, \beta]$, from 11.3 c, $\alpha + \beta$ is algebraic. A similar argument shows that $\alpha\beta$ is also algebraic.

We may generalize the notion of algebraic integer. If $R$ is a commutative ring and $S$ a subring, then we say that $\alpha \in R$ is integral over $S$ if there is a monic polynomial $f \in S[X]$ such that $f(\alpha) = 0$. With Theorem 11.3 as model we may establish criteria allowing us to decide whether an element of $R$ is integral over $S$.

Theorem 11.4 If $S$ is a subring of the commutative ring $R$, then the following conditions are equivalent for an element $\alpha \in R$:

- a. $\alpha$ is integral;
- b. The $S$-module $S[\alpha]$ is finitely generated;
- c. $\alpha$ belongs to a subring $U$ of $R$ containing $S$ which is a finitely generated $S$-module;
- d. There is a nonzero finitely generated $S$-module $N$ in $R$ such that $\alpha N \subseteq N$.

Proof a. $\implies$ b. If $\alpha$ is a root of a monic polynomial $f \in S[X]$ and $\deg f = n$, then $\alpha^n$ and all higher powers of $\alpha$ can be expressed as linear combinations (with coefficients in $S$) of lower powers of $\alpha$. Hence $S[\alpha]$ is generated by the elements $1, \alpha, \ldots, \alpha^{n-1}$.

b. $\implies$ c. $\implies$ d. These implications are elementary.

d. $\implies$ a. Suppose that $a_1, \ldots, a_n$ generate $N$. Then each term $\alpha a_i$ can be expressed as a linear combination of the $a_i$ with coefficients in $S$. Therefore there is a matrix $M \in M_n(S)$ such that

$$
\begin{pmatrix}
a_1 \\
a_2 \\
\vdots \\
a_n
\end{pmatrix}
= M
\begin{pmatrix}
a_1 \\
a_2 \\
\vdots \\
a_n
\end{pmatrix}
\implies (\alpha I_n - M)
\begin{pmatrix}
a_1 \\
a_2 \\
\vdots \\
a_n
\end{pmatrix}
= 0.
$$

As all the $a_i$ are nonzero, $\det(\alpha I - M) = 0$. However, this determinant can be written:

$$
\alpha^n + c_{n-1}\alpha^{n-1} + \cdots + c_1\alpha + c_0 = 0,
$$

with $c_i \in S$. Hence we have a monic polynomial $f \in S[X]$ such that $f(\alpha) = 0$.

Using arguments analogous to those employed in the proof of Corollary 11.2 we see that the collection of elements in $R$ which are integral over $S$ form a subring of $R$. We call this subring the integral closure of $S$ in $R$. If the integral closure is $S$ itself, then we say that $S$ is integrally closed in $R$. If $S$ is an integral domain and integrally closed in its field of fractions, then we say that $S$ is integrally closed. Above we saw that $Z$ is integrally closed in $Q$, its field of fractions, so $Z$ is integrally closed.

If $S$ is a subring of the ring $R$ such that every element of $R$ is integral over $S$, then we say that $R$ is integral over $S$.

The integral closure of $S$ in $R$ is naturally an $S$-module. We will now explore some of its properties. We first consider minimal polynomials over integrally closed domains.
Proposition 11.1 Let $R$ be an integrally closed domain, with field of fractions $K$, and $L$ an extension of $K$. If $x \in L$ is integral over $R$ and $L$ is a splitting field of the minimal polynomial $m = m(x, K)$, then all the $K$-conjugates of $x$ belong to $L$ and are also integral over $R$. It follows that $m \in R[X]$. If $S$ is the integral closure of $R$ in $L$, then $S \cap K = R$.

PROOF Let us write $\bar{R}$ for the integral closure of $R$ in $L$. Then $R \subset \bar{R} \cap K \subset R$, because $R$ is integrally closed. Thus $\bar{R} \cap K = R$.

If $x \in L$ is integral over $R$, then there exists a monic polynomial $f \in R[X]$ such that $f(x) = 0$. The minimal polynomial $m = m(x, K)$ divides $f$. It follows that the $K$-conjugates of $x$ (which are in $L$) are also roots of $f$, hence integral over $R$ and so belong to $\bar{R}$.

The coefficients of $m$ are, up to sign, defined by the elementary symmetric functions evaluated at the $K$-conjugates of $x$ and so belong to $\bar{R} \cap K = R$, i.e., $m \in R[X]$.

To finish, we consider the integral closure $S$ of $R$ in $L$. If $x \in S \cap K$, then $x \in R$, because $R$ is integrally closed, so $S \cap K \subset R$. Clearly $R \subset S \cap K$, so we have $S \cap K = R$.  

The next result concerns the field of fractions of an integral closure of an integral domain.

Proposition 11.2 Let $R$ be an integral domain and $K$ its field of fractions. If $L$ is an algebraic extension of $K$ and $S$ the integral closure of $R$ in $L$, then the field of fractions $F$ of $S$ is $L$.

PROOF Clearly $R \subset S \subset F \subset L$. As $F \subset L$, we only need to show that $L \subset F$. Let $x \in L$. If $x = 0$, then there is nothing to prove, so let us suppose that this is not the case. As $L$ is an algebraic extension of $K$, $x$ is algebraic over $K$: there exists a polynomial $f(X) = \sum_{i=0}^{m} a_i X^i \in K[X]$ such that $f(x) = 0$. Then $\sum_{i=0}^{m} \frac{a_i}{a_m} (a_m x)^i = 0$. Setting $b_i = \frac{a_i}{a_m}$, we obtain a monic polynomial $g \in K[X]$ such that $g(a_m x) = 0$. Hence $s = a_m x \in S$. As $K$ is the field of fractions of $R$, there exist $r_1, r_2 \in R$ such that $a_m = \frac{r_1}{r_2}$, so $x = \frac{a_m x}{r_2} \in F$, because $r_1, r_2 \in S$. Hence $L \subset F$.  

Corollary 11.3 If $R$, $K$, $L$ and $S$ are as in Proposition 11.2, then every element of $x$ of $L$ has the form $\frac{r}{s}$, where $s \in S$ and $r \in R^\times$.

PROOF For $x = 0$ there is nothing to prove, so we suppose that this is not the case. In the proof of Proposition 11.2 we showed that, if $x \in L$, then $x = \frac{a_m}{r_2}$, where $r_1, r_2 \in R$ and $s \in S$. As $R \subset S$, we have $sr_2 \in S$, hence the result.  

Exercise 11.2 Show that there exists a basis of $L$ over $K$ composed of elements in $S$.

We now introduce an interesting result, which we will use further on.

Theorem 11.5 Let $R$ be an integrally closed domain, $K$ its field of fractions and $L$ a separable extension of degree $n$ of $K$. Suppose that $S$ is the integral closure of $R$ in $L$. Then there exist free $R$-modules $M$ and $M'$, of rank $n$, such that $M' \subset S \subset M$.

PROOF Let $t$ be a primitive element of $L$ over $K$, i.e., $L = K(t)$. From Lemma 11.1, we may write $t = \frac{s}{r}$, with $s \in S$ and $r \in R^\times$. Thus $L = K(s)$. Since $L$ is an extension of degree $n$ of $K$, the degree of the minimal polynomial $m(s, K)$ is also $n$. Consequently, the elements $1, s, \ldots, s^{n-1}$ are $K$-independant. These elements are also $R$-independant elements of the $R$-module $S$. The $R$-submodule of $S$ generated by $1, s, \ldots, s^{n-1}$ is

$$M' = R \oplus Rs \oplus \cdots \oplus Rs^{n-1},$$

which is a free module of rank $n$.

112
It is a little more difficult to show that $S$ is contained in some free $R$-module. Let $d = \text{disc}_{L/K}(1, s, \ldots, s^{n-1})$. As the elements $1, s, \ldots, s^{n-1}$ are $K$-linearly independent, Proposition 10.8 ensures that $d \neq 0$. Then $\frac{1}{d}, \frac{s}{d}, \ldots, \frac{s^{n-1}}{d}$ are $R$-linearly independent elements of the $R$-module $L$. The $R$-module generated by these elements is

$$M = R\left(\frac{1}{d}\right) \oplus R\left(\frac{s}{d}\right) \oplus \cdots \oplus R\left(\frac{s^{n-1}}{d}\right).$$

$M$ is a free $R$-module of rank $n$. We aim to show that $S \subset M$. As the set $\{1, s, \ldots, s^{n-1}\}$ is a basis of $L$ over $K$, any $y \in S$ can be written

$$y = \sum_{j=0}^{n-1} c_j s^j = \sum_{j=0}^{n-1} dc_j \left(\frac{s^j}{d}\right),$$

where the $c_j \in K$. We need to show that $dc_j \in R$. Since $dc_j \in K$ and $R$ is an integrally closed domain, it is sufficient to prove that the $dc_j$ are integral over $R$.

Since $L$ is separable extension of $K$ of degree $n$, Corollary 3.2 ensures that there are $n$ distinct $K$-monomorphisms $\sigma_1, \ldots, \sigma_n$ from $L$ into an algebraic closure $C$ of $K$. As $L = K(s)$, each $\sigma_i$ is entirely determined by $\sigma_i(s)$, hence the elements $\sigma_1(s), \ldots, \sigma_n(s)$ are distincts. In addition, for $i = 1, \ldots, n$, $\sigma_i(s)$ is a $K$-conjugate of $s$ and so the set $\{\sigma_1(s), \ldots, \sigma_n(s)\}$ is equal to the set of $K$-conjugates $\{s_1, \ldots, s_n\}$ of $s$. Without loss of generality, we may suppose that $\sigma_i(s) = s_i$, for all $i$. Applying $\sigma_i$ to the equality $y = \sum_{j=0}^{n-1} c_j s^j$ we obtain, for all $i$,

$$\sigma_i(y) = \sum_{j=0}^{n-1} c_j (\sigma_i(s))^j = \sum_{j=0}^{n-1} c_j s_i^j.$$

We may express this in matrix form:

$$\begin{pmatrix} \sigma_1(y) \\ \vdots \\ \sigma_n(y) \end{pmatrix} = \begin{pmatrix} 1 & s_1 & \cdots & s_1^{n-1} \\ \vdots & \vdots & \ddots & \vdots \\ 1 & s_n & \cdots & s_n^{n-1} \end{pmatrix} \begin{pmatrix} c_0 \\ \vdots \\ c_{n-1} \end{pmatrix}.$$

The matrix $V = (s_i^j)$ is a Vandermonde matrix with all $s_i$ distinct, so its determinant $\delta$ does not vanish. Using Cramer’s rule, we obtain expressions for the $c_j$, namely $c_j = \frac{\gamma_j}{\delta}$, where $\gamma_j$ is the determinant of the matrix $V_j$ obtained from $V$ by replacing the column $j+1$ by the column $(\sigma_1(y), \ldots, \sigma_n(y))^t$.

Now, from Proposition 10.9, $d = \text{disc}_{L/K}(1, s, \ldots, s^{n-1})$ is the discriminant of the minimal polynomial $m(s, K)$; hence, using the formula for the determinant of a Vandermonde matrix, we obtain

$$d = \prod_{1 \leq i < j \leq n} (s_i - s_j)^2 = \delta^2 \implies dc_j = \delta \gamma_j,$$

for $j = 0, \ldots, n - 1$. As $\delta$ and $\gamma_j$ are determinants of matrices with coefficients in $S$, because $y$ and $s$ belong to $S$. Therefore the $dc_j$ are integral over $R$, as required.

**11.2 Number rings**

Let $K$ be a number field and let us note $O_K$ the collection of algebraic integers in $K$. Clearly $O_K = \mathcal{O} \cap K$ and so, being the intersection of two subrings of $\mathcal{C}$, $O_K$ is a subring of $\mathcal{C}$. We
say that $O_K$ is the number ring associated to $K$ or the ring of integers of $K$. We will see that this ring has many interesting properties. However, let us first consider a "simple" case, namely that of number rings associated to quadratic number fields. We know that, if $K$ is a quadratic number field, then there is squarefree integer $d$ such that $K = \mathbb{Q}(\sqrt{d})$ (Theorem 3.5). It would be natural to think that associated number ring has the form $\mathbb{Z}[\sqrt{d}]$. The next theorem shows that $O_{\mathbb{Q}(\sqrt{d})}$ always contains $\mathbb{Z}[\sqrt{d}]$, but inclusion can be strict.

**Theorem 11.6** Let $d$ be a squarefree integer. Then

$$O_{\mathbb{Q}(\sqrt{d})} = \begin{cases} \mathbb{Z}[\sqrt{d}] & \text{if } d \equiv 2, 3 \pmod{4} \\ \mathbb{Z}[\frac{-1+\sqrt{d}}{2}] & \text{if } d \equiv 1 \pmod{4}. \end{cases}$$

**Proof** Case 1: $d = 2, 3 \pmod{4}$. We take $\alpha = r + s\sqrt{d} \in O_{\mathbb{Q}(\sqrt{d})}$. If $s = 0$, then $\alpha \in \mathbb{Q}$, hence, from Theorem 11.2 $\alpha \in \mathbb{Z}$, and so $\alpha \in \mathbb{Z}[\sqrt{d}]$. Now suppose that $s \neq 0$. We note

$$f(X) = (r^2 - ds^2) - 2rX + X^2 \in \mathbb{Q}[X].$$

Then $\Delta(f) = 4ds^2$. As $d$ is squarefree, $\Delta(f)$ is not a square in $\mathbb{Q}$, hence $f$ is irreducible. Now, $f(\alpha) = 0$, therefore $f = m(\alpha, \mathbb{Q})$. From Corollary 11.1, $f \in \mathbb{Z}[X]$ and so $r^2 - ds^2, 2r \in \mathbb{Z}$. This implies that $4ds^2 \in \mathbb{Z}$. Using the fact that $d$ is squarefree, we obtain $2s \in \mathbb{Z}$. Let us note $m = 2r$ and $n = 2s$. Then

$$r^2 - ds^2 = \frac{1}{4}(m^2 - dn^2) \in \mathbb{Z}$$

and so $4|(m^2 - dn^2)$. Then

$$d \equiv 2 \pmod{4} \implies m^2 - dn^2 \equiv m^2 + 2n^2 \pmod{4}$$

and

$$d \equiv 3 \pmod{4} \implies m^2 - dn^2 \equiv m^2 + n^2 \pmod{4}.$$  

As $m^2 - dn^2 \equiv 0 \pmod{4}$, in both cases $m$ and $n$ are even, which implies that $r, s \in \mathbb{Z}$. Thus $\alpha \in \mathbb{Z}[\sqrt{d}]$.

Suppose now that $\alpha = r + s\sqrt{d}$, with $r, s \in \mathbb{Z}$. If $s = 0$, then $\alpha \in \mathbb{Z} \subset O_{\mathbb{Q}(\sqrt{d})}$. If $s \neq 0$, then $r^2 - ds^2, 2r \in \mathbb{Z}$ and so $f \in \mathbb{Z}[X]$; as $f(\alpha) = 0$, it follows that $\alpha \in O_{\mathbb{Q}(\sqrt{d})}$.

We have proved the result for the case $d \equiv 2, 3 \pmod{4}$.

Case 2: $d = 1 \pmod{4}$. We take $\alpha = r + s\sqrt{d} \in O_{\mathbb{Q}(\sqrt{d})}$. If $s = 0$, then $\alpha \in \mathbb{Q}$, hence, from Theorem 11.2, $\alpha \in \mathbb{Z}$ and so $\alpha \in \mathbb{Z}[\frac{-1+\sqrt{d}}{2}]$. To handle the case where $s \neq 0$, we define $f \in \mathbb{Q}[X]$ as above and proceed as in Case 1 to find $4(m^2 - dn^2)$, where $m = 2r$ and $n = 2s$.

$$d \equiv 1 \pmod{4} \implies m^2 - dn^2 \equiv m^2 - n^2 \pmod{4}.$$  

Thus we have $4|(m^2 - dn^2)$ and $4|(m^2 - n^2)$, which implies that $m$ and $n$ have the same parity. Now,

$$\alpha = \frac{m + n\sqrt{d}}{2} = \frac{m}{2} + n \left(\frac{-1 + \sqrt{d}}{2}\right) \in \mathbb{Z}[\frac{-1 + \sqrt{d}}{2}].$$

Now suppose that $\alpha = r + s\frac{-1 + \sqrt{d}}{2}$, with $r, s \in \mathbb{Z}$. If $s = 0$, then $\alpha \in \mathbb{Z} \subset O_{\mathbb{Q}(\sqrt{d})}$. For the case where $s \neq 0$ we have $2r, r^2 - ds^2 \in \mathbb{Z}$, so $f \in \mathbb{Z}[X]$; as $f(\alpha) = 0$, it follows that $\alpha \in O_{\mathbb{Q}(\sqrt{d})}$.

This proves the result for $d \equiv 1 \pmod{4}$.

**Examples**
• \( \mathbb{O}_{\mathbb{Q}(i)} = \mathbb{Z}[i] \), because \(-1 \equiv 3 \pmod{4}\);
• \( \mathbb{O}_{\mathbb{Q}(\sqrt{3})} = \mathbb{Z}[\sqrt{3}] \), because \(3 \equiv 3 \pmod{4}\);
• \( \mathbb{O}_{\mathbb{Q}(\sqrt{5})} = \mathbb{Z}[\frac{-1+i\sqrt{5}}{2}] \), because \(5 \equiv 1 \pmod{4}\);
• \( \mathbb{O}_{\mathbb{Q}(\sqrt{6})} = \mathbb{Z}[\sqrt{6}] \), because \(6 \equiv 2 \pmod{4}\).

We now consider certain basis properties of number rings. In particular, we will show that the additive group of such a ring is a free abelian group. We begin with a characterization of invertible elements.

**Proposition 11.3** If \( K \) is a number field and \( \alpha \in \mathbb{O}_K \), then \( \alpha \in \mathbb{O}_K^\times \) if and only if \( N_{K/\mathbb{Q}}(\alpha) = \pm 1 \).

**Proof** If \( \alpha \in \mathbb{O}_K^\times \), then \( \alpha^{-1} \in \mathbb{O}_K^\times \) and

\[
1 = N_{K/\mathbb{Q}}(1) = N_{K/\mathbb{Q}}(\alpha)N_{K/\mathbb{Q}}(\alpha^{-1}).
\]

As \( \alpha \) and \( \alpha^{-1} \) are algebraic, \( N_{K/\mathbb{Q}}(\alpha) \) and \( N_{K/\mathbb{Q}}(\alpha^{-1}) \) are integers, hence \( N_{K/\mathbb{Q}}(\alpha) = \pm 1 \).

Now suppose that \( N_{K/\mathbb{Q}}(\alpha) = \pm 1 \). Since \( \alpha \in \mathbb{O}_K \), Proposition 10.1 and Corollary 11.1 ensure that \( \text{char}_{K/\mathbb{Q}}(\alpha) \) belongs to \( \mathbb{Z}[X] \). Thus we have

\[
\text{char}_{K/\mathbb{Q}}(\alpha) = \pm 1 + a_1 X + \cdots + a_{n-1} X^{n-1} + X^n,
\]

with \( a_i \in \mathbb{Z} \), for \( 1 \leq i \leq n - 1 \). From the Cayley-Hamiltonian Theorem, we know that \( \alpha \) is a root of \( \text{char}_{K/\mathbb{Q}}(\alpha) \).

Now \( \alpha^{-1} \) is a root of the reciprocal polynomial

\[
f(X) = 1 + a_{n} X + \cdots + a_1 X^{n-1} \pm X^n.
\]

Since \( f \in \mathbb{Z}[X] \), \( \alpha^{-1} \) is algebraic and it follows that \( \alpha \in \mathbb{O}_K^\times \). \( \square \)

**Exercise 11.3** Show that, if \( K = \mathbb{Q}(\sqrt{-2}) \), then \( \mathbb{O}_K^\times \) is finite. Considering the positive powers of \( 1 + \sqrt{2} \), show that the diophantine equation \( a^2 - 2b^2 = 1 \) has an infinite number of solutions and deduce that, if \( K = \mathbb{Q}(\sqrt{2}) \), then \( \mathbb{O}_K^\times \) is infinite.

As \( \mathbb{O}_K \) is an integral domain, it has a field of fractions (in \( \mathbb{C} \)). It is natural to try to determine this field. We will now do.

**Lemma 11.2** If \( \alpha \in \mathbb{C} \) is algebraic over \( \mathbb{Q} \), then there is an integer \( k \in \mathbb{N}^\ast \) such that \( k\alpha \) is an algebraic integer.

**Proof** If \( \alpha = 0 \), then there is nothing to prove, so let us suppose that this is not the case. Let \( m(X) = \sum_{i=0}^{d-1} a_i X^i + X^d \) be the minimal polynomial of \( \alpha \) over \( \mathbb{Q} \). If \( k \) is the lcm of the denominators of the coefficients \( a_i \), then \( ka_i = b_i \in \mathbb{Z} \), for \( 0 \leq i \leq d - 1 \). We have

\[
k^{d-1}b_0 + k^{d-2}b_1(k\alpha) + \cdots + kb_{d-2}(k\alpha)^{d-2} + b_{d-1}(k\alpha)^{d-1} + (k\alpha)^d = k^d m(\alpha) = 0.
\]

As the coefficients \( k^{d-1}b_0, \ldots, kb_{d-2}, b_{d-1} \) are integers, \( k\alpha \) is an algebraic integer. \( \square \)
Theorem 11.7 The field of fractions of $O_K$ is the number field $K$.

PROOF Let us write $L$ for the field of fractions of $O_K$. The clearly $O_K \subset K$. If $L \neq K$, then there exists $\alpha \in K \setminus L$. As $K$ is a finite extension of $Q$, $K$ is algebraic over $Q$. In particular, $\alpha$ is algebraic over $Q$. From Lemma 11.2, there exists $k \in \mathbb{N}^*$ such that $k\alpha$ is an algebraic integer, hence $k\alpha \in O_K \subset L$. As $k \in O_K$, $\alpha = \frac{k\alpha}{K} \in L$, a contradiction.

We now consider bases of the vector space $K$ over $Q$. It turns out that there is a basis composed entirely of elements in $O_K$.

Proposition 11.4 If $K$ is a number field, and $[K : Q] = n$, then $K$ has a basis $\alpha_1, \ldots, \alpha_n$ composed of elements in $O_K$.

PROOF From Lemma 11.2, we know that, if $\alpha$ is nonzero and algebraic over $Q$, then there in an integer $k \in \mathbb{N}^*$ such that $k\alpha$ is an algebraic integer. Let $(\beta_1, \ldots, \beta_n)$ be a basis of $K$ over $Q$. As $K$ is a finite extension of $Q$, $K$ is algebraic over $Q$ and so each $\beta_i$ is algebraic over $Q$. For each $\beta_i$, we may find $k_i \in \mathbb{N}^*$ such that $k_i\beta_i$ is an algebraic integer. If $\alpha_i = k_i\beta_i$, then clearly $(\alpha_1, \ldots, \alpha_n)$ is a basis of $K$ over $Q$.

We now turn to the result referred to above concerning the nature of the additive group of $O_K$. To understand the proof it is necessary to have a knowledge of free abelian groups. We have included an appendix on the subject.

Theorem 11.8 The additive group of $O_K$ is a free abelian group of rank $n$.

PROOF Let $(\alpha_1, \ldots, \alpha_n)$ be a basis of $K$ over $Q$ composed of elements of $O_K$ and $A = \mathbb{Z}\alpha_1 \oplus \cdots \oplus \mathbb{Z}\alpha_n$. (The sum is direct because the $\alpha_i$ are independent over $Q$.) If we can show that there exists $d \in \mathbb{Z}^*$ such that $dO_K \subset A$, then the theorem is proved. Indeed, in this case, $O_K \subset \frac{1}{d}A$, where $\frac{1}{d}A$ is a free abelian group. Thus, by Theorem E.3, $O_K$ is a free abelian group of rank $r$, with $r \leq n$. Moreover, $A$ is subgroup of $O_K$ and so, using Theorem E.3 again, the rank of $r$ of $O_K$ is larger than $n$. Finally, $O_K$ is a free abelian group of rank $n$.

Let us now show that this $d$ exists. For any $\alpha \in O_K$, there exist $x_1, \ldots, x_n \in Q$ such that $\alpha = \sum_{i=1}^n x_i\alpha_i$. We set $d = \text{disc}_{K/Q}(\alpha_1, \ldots, \alpha_n)$; then $d$ is nonzero by Proposition 10.8. Using Proposition 10.7 and Exercise 11.1 we see that $d$ is an integer, since the algebraic integers form a ring.

We now show that $dx_i \in \mathbb{Z}$, for $1 \leq i \leq n$, which implies that $d\alpha \in A$. We note $\sigma_1, \ldots, \sigma_n$ the $Q$-monomorphisms of $K$ into $C$. We have, for $1 \leq i \leq n$,

$$\sigma_i(\alpha) = x_1\sigma_i(\alpha_1) + \cdots + x_n\sigma_i(\alpha_n).$$

This is a system of $n$ equations in $n$ unknowns ($x_j$). Applying Cramer’s rule we obtain

$$x_j = \frac{\nu_j}{\delta},$$

where $\delta$ is the determinant $|\sigma_j(\alpha_j)|$ and $\nu_j$ is the determinant of the matrix obtained from the matrix $(\sigma_i(\alpha_j))$ by replacing the $j$th column by the column composed of the elements $\sigma_i(\alpha)$. Now, $\delta^2 = d$, so $\delta$ is an algebraic integer. In the same way, we may show that $\nu_j$ is an algebraic integer, since

$$\nu_j^2 = \text{disc}_{K/Q}(\alpha_1, \ldots, \alpha_{j-1}, \alpha, \alpha_{j+1}, \ldots, \alpha_n),$$

116
and \( \alpha \in O_K \). To finish, we notice that

\[
dx_j = \delta^2 \nu_j = \delta \nu_j
\]

which implies that \( dx_j \) is an algebraic integer, since both \( \delta \) and \( \nu_j \) are algebraic integers. Moreover, \( dx_j \in \mathbb{Q} \). As an algebraic integer in \( \mathbb{Q} \) is an integer, \( dx_j \) is an integer. This concludes the proof.

**Discriminant of a number ring**

Let \( K \) be a number field with number ring \( O_K \). As \( O_K \) is a free abelian group, \( O_K \) has a basis \( (\alpha_1, \ldots, \alpha_n) \), where \( n \) is the dimension of the vector space \( K \) over \( \mathbb{Q} \):

\[
O_K = \mathbb{Z} \alpha_1 \oplus \cdots \oplus \mathbb{Z} \alpha_n.
\]

We call such a basis an integral basis. There may be many bases; however, they are related through their discriminants.

**Proposition 11.5** If \( (\alpha_1, \ldots, \alpha_n) \) and \( (\beta_1, \ldots, \beta_n) \) are integral bases of \( O_K \), then

\[
\text{disc}_{\mathbb{Q}}(\alpha_1, \ldots, \alpha_n) = \text{disc}_{\mathbb{Q}}(\beta_1, \ldots, \beta_n).
\]

**Proof** First we notice that there is a matrix \( M = (m_{ij}) \in \mathcal{M}_n(\mathbb{Z}) \) such that

\[
\begin{pmatrix}
\alpha_1 \\
\vdots \\
\alpha_n
\end{pmatrix} = M \begin{pmatrix}
\beta_1 \\
\vdots \\
\beta_n
\end{pmatrix}
\]

Let \( \sigma_1, \ldots, \sigma_n \) be the \( \mathbb{Q} \)-monomorphisms of \( K \) into \( \mathbb{C} \). Then

\[
\alpha_i = \sum_{k=1}^{n} m_{ik} \beta_k \implies \sigma_j(\alpha_i) = \sum_{k=1}^{n} m_{ik} \sigma_j(\beta_k),
\]

for \( 1 \leq i, j \leq n \). In terms of matrices,

\[
(\sigma_j(\alpha_i)) = M (\sigma_j(\beta_k)),
\]

which implies that

\[
\text{disc}_{\mathbb{Q}}(\alpha_1, \ldots, \alpha_n) = |M|^2 \text{disc}_{\mathbb{Q}}(\beta_1, \ldots, \beta_n).
\]

As the \( \alpha_i \) and \( \beta_j \) are algebraic integers, from Proposition 10.7, the discriminants in the above equations are integers. Given that \( M \in \mathcal{M}_n(\mathbb{Z}) \), the determinant \( |M| \) is an integer and it follows that \( \text{disc}_{\mathbb{Q}}(\beta_1, \ldots, \beta_n) \) divides \( \text{disc}_{\mathbb{Q}}(\alpha_1, \ldots, \alpha_n) \). In the same way, \( \text{disc}_{\mathbb{Q}}(\alpha_1, \ldots, \alpha_n) \) divides \( \text{disc}_{\mathbb{Q}}(\beta_1, \ldots, \beta_n) \). As the discriminants clearly have the same sign, they are equal.

We call the common value of the discriminant in the foregoing theorem the discriminant of the number ring \( O_K \) and we write \( \text{disc}(O_K) \) for this. We emphasize that \( \text{disc}(O_K) \in \mathbb{Z} \).

**Example** Let \( K = \mathbb{Q}(\sqrt{d}) \), where \( d \) is a squarefree integer. The Galois group \( \text{Gal}(K/\mathbb{Q}) = (\sigma_1, \sigma_2) \), where \( \sigma_1 \) is the identity and \( \sigma_2 \) permutes \( \sqrt{d} \) and \( -\sqrt{d} \). If \( d \equiv 2, 3 \) (mod 4), then \( O_K = \mathbb{Z}[\sqrt{d}] \) and \( (1, \sqrt{d}) \) is an integral basis of \( O_K \). It follows that

\[
\text{disc}(O_K) = \text{disc}_{\mathbb{Q}}(1, \sqrt{d}) = 4d.
\]
Exercise 11.4 Show that, if \( d \equiv 1 \pmod{4} \), then \( \text{disc}(O_K) = d \).

We may extend the notion of the discriminant of a number ring. Let \( K \) be a number field with ring of integers \( O_K \). An order in \( K \) is a subring \( R \) of \( O_K \) such that the index of \( R \) in \( O_K \) (as additive groups) is finite. The order is said to be maximal if \( R = O_K \).

If \( R \) is a subring of \( O_K \), from Theorem E.3 we know that \( R \) is a free group with rank at most that of \( O_K \).

Proposition 11.6 A subring \( R \) of \( O_K \) is an order if and only if \( R \) has the same rank as that of \( O_K \).

Proof Let \( n \) be the rank of \( O_K \) and \( r \) that of \( R \). From Theorem E.4, \( O_K \) has a basis \( \{e_1, \ldots, e_n\} \) for which there exist integers \( d_1, \ldots, d_r \in \mathbb{N}^* \), such that \( \{d_1 e_1, \ldots, d_r e_r\} \) is a basis of \( R \). If \( r = n \), then the cosets of \( R \) in \( O_K \) can be written
\[
s_1 e_1 + \cdots + s_n e_n + R, \quad \text{with} \quad 0 \leq s_1 \leq d_1 - 1, \ldots, 0 \leq s_n \leq d_n - 1.
\]
Thus there are \( d_1 \cdots d_n \) cosets, i.e., \( [O_K : R] < \infty \) and \( R \) is an order. If \( r < n \), then the cosets of \( R \) in \( O_K \) may be written
\[
s_1 e_1 + \cdots + s_r e_r + x_{r+1} e_{r+1} + \cdots + x_n e_n + R,
\]
with \( 0 \leq s_i \leq d_i - 1, \ldots, 0 \leq x_r \leq d_r - 1 \) and \( x_{r+1}, \ldots, x_n \in \mathbb{Z} \). In this case there is an infinite number of cosets, so \([O_K : R] = \infty \) and \( R \) is not an order.

If \( R \subset O_K \) is an order, then we may define the discriminant of \( R \) in the same way as we did for \( O_K \). If \( (\alpha_1, \ldots, \alpha_n) \) and \( (\beta_1, \ldots, \beta_n) \) are integral bases of \( R \), then the argument of Proposition 11.5 shows that
\[
\text{disc}_{K/Q}(\alpha_1, \ldots, \alpha_n) = \text{disc}_{K/Q}(\beta_1, \ldots, \beta_n),
\]
and that the common value is an integer. We call this the discriminant of \( R \) and note it \( \text{disc}(R) \).

Example Suppose that \( K = \mathbb{Q}(\alpha) \), where \( \alpha \in O_K \). Then \( \text{rk} O_K = [\mathbb{Q}(\alpha) : \mathbb{Q}] \). However, \( \text{deg} m(\alpha, \mathbb{Q}) = n = [\mathbb{Q}(\alpha) : \mathbb{Q}] \), so the set \( \{1, \alpha, \ldots, \alpha^{n-1}\} \) is a basis of \( \mathbb{Z}[\alpha] \). Thus \( \mathbb{Z}[\alpha] \) and \( O_K \) have the same rank: \( \mathbb{Z}[\alpha] / n \) is an order in \( K \).

We will return to orders further on.

We say that an integral domain \( D \) is a normal domain if the integral closure of \( D \) in its field of fractions is \( D \) itself. It is worth noticing (although we will not prove it here) that the polynomial ring \( D[X] \) is a normal domain if \( D \) is normal. We aim to show that a number ring is a normal domain. We will first prove a preliminary result, which is interesting in its own right.

Lemma 11.3 A subgroup of a finitely generated abelian group is finitely generated.

Proof We will use an induction on the number of generators. Let \( G \) be a finitely generated abelian group: \( G = \langle a_1, \ldots, a_n \rangle \). If \( n = 1 \), then \( G \) is cyclic. As a subgroup of a cyclic group is cyclic, the result is true in the case \( n = 1 \).

Now suppose that we have proved the result up to \( n \) and \( G = \langle a_1, \ldots, a_n, a_{n+1} \rangle \). Let \( H \) be a subgroup of \( G \) and \( \pi : G \to G/(a_{n+1}) \) the canonical quotient mapping. As \( G \) is abelian, the quotient \( \bar{G} = G/(a_{n+1}) \) has a natural group structure and \( \bar{G} = \langle \pi(a_1), \ldots, \pi(a_n) \rangle \). From the
induction hypothesis, the subgroup $\bar{H} = \pi(H)$ of $\bar{G}$ is finitely generated: $\bar{H} = \langle h_1, \ldots, h_m \rangle$, with $h_i = \pi(h_i)$ for some $h_i \in H$.

We now notice that $H \cap \langle a_{n+1} \rangle$ is a subgroup of $\langle a_{n+1} \rangle$, hence cyclic: $H \cap \langle a_{n+1} \rangle = \langle h_{m+1} \rangle$, with $h_{m+1} \in H$. We claim that $H = \langle h_1, \ldots, h_m, h_{m+1} \rangle$. If $h \in H$, then there exists $g \in \langle a_1, \ldots, h_m \rangle$ such that $\pi(g) = \pi(h)$. Therefore $h = g + k$, with $k \in \ker \pi = \langle a_{n+1} \rangle$. In addition, $k = h - g \in H$, so $k = sh_{m+1}$, for some $s \in \mathbb{Z}$. To conclude,

$$h = g + sh_{m+1} \in \langle h_1, \ldots, h_{m+1} \rangle.$$  

We have shown that $H = \langle h_1, \ldots, h_{m+1} \rangle$.  

**Remark** The abelian hypothesis in the previous lemma is important. Here is a counter-example. Theorems 11.2 and 11.3 ensure that the additive group of the ring $\mathbb{Z}[\frac{1}{2}]$ is not finitely generated. Consequently the group of matrices

$$G_0 = \{ \begin{pmatrix} 1 & x \\ 0 & 1 \end{pmatrix} \in \mathcal{M}_2(\mathbb{Q}), x \in \mathbb{Z}[\frac{1}{2}] \}$$

is not finitely generated. However, the elements of $\mathbb{Z}[\frac{1}{2}]$ are of the form $\frac{p}{2^q}$, with $p \in \mathbb{Z}$ and $q \in \mathbb{N}$, and

$$\begin{pmatrix} 1 & \frac{p}{2^q} \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} 2 & 0 \\ 0 & 1 \end{pmatrix}^{-q} \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}^{-m_1} \begin{pmatrix} 2 & 0 \\ 0 & 1 \end{pmatrix}^q \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}^{-m_2},$$

where $m_2$ and $m_1$ are respectively the quotient and remainder after division of $p$ by $2^q$. Hence $G_0$ is a subgroup of $G$, the subgroup of $\mathcal{M}_2(\mathbb{Q})$ generated by the matrices

$$S = \begin{pmatrix} 2 & 0 \\ 0 & 1 \end{pmatrix} \quad \text{and} \quad T = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}.$$  

Thus we have a subgroup of a finitely generated group which is not finitely generated.

**Exercise 11.5** Find an explicit description of the matrices in $G$.

**Proposition 11.7** A number ring $O_K$ is a normal domain.

**Proof** We have seen that $O_K$ has a finite basis. Let $\alpha \in K$ be integral over $O_K$: there exists a polynomial $f(X) = \sum_{i=0}^n a_i X^i + X^n$, with $a_i \in O_K$, such that $f(\alpha) = 0$. This implies that

$$\alpha^n = -a_{n-1} \alpha^{n-1} - \cdots - a_1 \alpha - a_0.$$  

It follows that the additive group of the ring $O_K[\alpha]$ is finitely generated. As $\mathbb{Z}[\alpha] \subset O_K[\alpha]$, the additive subgroup of the ring $\mathbb{Z}[\alpha]$ is also finitely generated (Lemma 11.3). From Theorem 11.3, $\alpha$ is an algebraic integer and so $\alpha \in O_K$.  

**Stickelberger’s criterion**

We may say a little more about the discriminant of a number ring. Let $K$ be a number field of degree $n$ over $\mathbb{Q}$ and $\mathcal{B} = \{ \beta_1, \ldots, \beta_n \}$ an integral basis of the number ring $O_K$. There exist $n$ $\mathbb{Q}$-embeddings $\sigma_1, \ldots, \sigma_n$ of $K$ in $\mathbb{C}$. By definition,

$$\text{disc}(O_K) = \text{det}(\sigma_i(\beta_j))^2.$$  

119
The determinant is the sum of expressions of the form
\[ \text{sgn}(\pi)\sigma_{\pi(1)}(\beta_1) \cdots \sigma_{\pi(n)}(\beta_n), \]
where \( \pi \) is a permutation of the set \( \{1, \ldots, n\} \), i.e., \( \pi \in S_n \), and \( \text{sgn}(\pi) \) is the sign of \( \pi \). To simplify the notation, let us set \( X = A_n \) and \( Y = S_n \setminus A_n \). Then
\[
\det(\sigma_i(\beta_j)) = \sum_{\pi \in S_n} \prod_{i=1}^n \text{sgn}(\pi)\sigma_{\pi(i)}(\beta_i) = \sum_{\pi \in X} \prod_{i=1}^n \sigma_{\pi(i)}(\beta_i) - \sum_{\pi \in Y} \prod_{i=1}^n \sigma_{\pi(i)}(\beta_i) = P - N.
\]

Thus
\[
\text{disc}(O_K) = (P - N)^2 = (P + N)^2 - 4PN.
\]

Now let \( L \) be a normal closure of \( K \) over \( Q \). By Exercise 5.1, \( L \) is a finite Galois extension of \( Q \). We aim to show that \( \phi(P + N) = P + N \) and \( \phi(PN) = PN \), for all \( \phi \in \text{Gal}(L/Q) \), the Galois group of \( L \) over \( Q \). First, we extend every embedding \( \sigma_i \) to an embedding \( \sigma_i \) of \( L \) into \( C \). (This is possible by Theorem 2.7.) From the normality of the extension \( L/Q \) we deduce that \( \sigma_i(L) = L \). (The image of \( \sigma_i \) is included in the set \( \text{A}(C/Q) \), which is an algebraic closure of \( Q \), by the remark after Theorem 2.6; therefore, from Proposition 5.2), \( \sigma_i(L) = L \). It follows that \( \sigma_i(K) \subset L \). Hence, for every \( \sigma_i \), the mapping \( \phi \circ \sigma_i \) is defined and is a \( Q \)-embedding of \( K \) into \( C \).

We now notice that the mapping \( \sigma_i \mapsto \phi \circ \sigma_i \) is a bijection on the set \( S = \{\sigma_1, \ldots, \sigma_n\} \), so we can find a permutation \( \tau \in S_n \) such that \( \phi \circ \sigma_i = \sigma_{\tau(i)} \), for every \( i \in \{1, \ldots, n\} \). We distinguish two cases:

**Case 1: \( \tau \) even**

Here we have \( \tau X = X \) and
\[
\phi \left( \sum_{\pi \in X} \prod_{i=1}^n \sigma_{\pi(i)}(\beta_i) \right) = \sum_{\pi \in X} \prod_{i=1}^n \phi \circ \sigma_{\pi(i)}(\beta_i)
\]
\[
= \sum_{\pi \in X} \prod_{i=1}^n \sigma_{\tau \pi(i)}(\beta_i)
\]
\[
= \sum_{\pi \in \tau X} \prod_{i=1}^n \sigma_{\pi(i)}(\beta_i)
\]
\[
= \sum_{\pi \in \tau X} \prod_{i=1}^n \sigma_{\pi(i)}(\beta_i).
\]

Hence \( \phi(P) = P \). In a similar way, using the fact that \( \tau Y = Y \), we may show that \( \phi(N) = N \).

**Case 2: \( \tau \) odd**

Now we have \( \tau X = Y \) and \( \tau Y = X \) and so \( \phi(P) = N \) and \( \phi(N) = P \).

From what we have seen, in both cases we have \( \phi(P + N) = P + N \) and \( \phi(PN) = PN \).

This applies for any \( \phi \in \text{Gal}(L/Q) \), so \( P + N \) and \( PN \) belong to the fixed field of \( \text{Gal}(K/Q) \), i.e., \( Q \). Now the \( \beta_i \) are algebraic integers; since the elements \( \sigma_{\pi(i)}(\beta_i) \) are roots of the minimal polynomial \( m(\beta_i, Q) \), these elements are also algebraic integers. This means that \( P \) and \( N \) are algebraic integers in \( Q \), i.e., integers. From the formula
\[
\text{disc}(O_K) = (P + N)^2 - 4PN,
\]
120
we may deduce the following: If $P$ and $N$ have the same parity, then $P + N \equiv 0 \ (\text{mod } 2) \implies (P + N)^2 \equiv 0 \ (\text{mod } 4)$; if $P$ and $N$ have different parities, then $P + N \equiv 1 \ (\text{mod } 2) \implies (P + N)^2 \equiv 1 \ (\text{mod } 4)$. Thus we have:

**Theorem 11.9** (Stickelberger’s criterion) If $K$ is a number field, with number ring $O_K$, then

$$\text{disc}(O_K) \equiv 0 \ (\text{mod } 4) \text{ or } \text{disc}(O_K) \equiv 1 \ (\text{mod } 4).$$

**Remark** In a certain sense Stickelberger’s theorem generalizes Exercise 11.4 and the remark preceding it.

### 11.3 Roots of unity in number fields

In any commutative ring with identity, the roots of unity form a multiplicative group. In a number field, as we will soon see, this group is cyclic. If $K$ is a number field and $x$ is a root of unity, then $-1 + x^n = 0$, for some $n \in \mathbb{N}^*$, so $x$ lies in the number ring $O_K$.

**Proposition 11.8** Let $K$ be a number field and $c \in \mathbb{R}_+^*$. Then there are only a finite number of elements $x \in O_K$ such that $|x| \leq c$, for all conjugates $x^{(i)}$ of $x$.

**Proof** Let $[K : \mathbb{Q}] = n$ and $\Sigma_1, \ldots, \Sigma_n$ be the elementary symmetric polynomials in $n$ variables. We set

$$c' = \max\{nc, \left(\frac{n}{2}\right)c^2, \ldots, \left(\frac{n}{k}\right)c^k, \ldots, c^n\}.$$ 

Let $S$ be the set of monic polynomials of degree at most $n$, whose coefficients are integers $a$ such that $|a| \leq c'$. Then $S$ is finite. Now let $T$ be the set of elements of $K$ which are roots of some polynomial belonging to $S$; $T$ is also a finite set. If $|x^{(i)}| \leq c$, for all conjugates of $x$ in $K$, then $|\Sigma_k(x^{(1)}, \ldots, x^{(n)})| \leq c'$, for $k = 1, \ldots, n$. Since $x$ is an algebraic integer, $\Sigma_k(x^{(1)}, \ldots, x^{(n)}) \in \mathbb{Z}$ and so the polynomial $f(X) = \prod_{i=1}^n (-x^{(i)} + X)$ belongs to $S$. As $x$ is a root of $f$, $x$ belongs to $T$.

We may now prove a fundamental result.

**Theorem 11.10** The group $W$ of roots of unity of a number field $K$ is a finite multiplicative cyclic group.

**Proof** It is sufficient to notice that $W$ is a finite subgroup of the multiplicative group of $K$ and apply Theorem 3.3.

The next result gives us a criterion for determining roots of unity.

**Proposition 11.9** If $f \in \mathbb{Z}[X]$ is monic and is such that all its roots in $\mathbb{C}$ have absolute value 1. Then these roots are all roots of unity.

**Proof** Let $z_1, \ldots, z_k$ be the roots of $f$ in $\mathbb{C}$ repeated according to their multiplicities. For every $l \in \mathbb{N}^*$ we set

$$f_l(X) = (-z_1^l + X) \cdots (-z_k^l + X).$$

From Exercise B.1, $f_l \in \mathbb{Z}[X]$ for all $l$. If

$$f_l(X) = a_0 + a_1 X + \cdots + a_{k-1} X^{k-1} + X^k,$$
then, taking into account the fact that \(|z_i| = 1\) for all \(i\), we find that
\[
|a_j| \leq \binom{k}{j}
\]
for \(j = 0, 1, \ldots, k - 1\). There are only a finite number of monic polynomials \(g \in \mathbb{Z}[X]\) with \(\deg g = k\) and \(j\)th coefficient bounded by \(\binom{k}{j}\) for \(j = 0, 1, \ldots, k - 1\), hence there exist \(l < m\) such that \(f_l = f_m\). It follows that the roots of these two polynomials are the same. If \(z_1, \ldots, z_r\) are the distinct roots of \(f_l\) and \(z_1^m, \ldots, z_r^m\) the distinct roots of \(f_m\), then there exists a permutation \(\sigma \in \Sigma_r\) such that \(z_i^l = z_{\sigma(i)}^m\), for \(i = 1, \ldots, r\). We claim that \(z_i^k = z_{\sigma(i)}^m\), for \(k \in \mathbb{N}^*\). For this we give a proof by induction. For \(k = 1\), there is nothing to prove. Suppose now that the result is true for \(k\) and consider the case \(k + 1\). We have
\[
z_{\sigma^{k+1}(i)}^m = z_{\sigma^k(i)}^m = (z_{\sigma^k(i)}^l)^m = (z_{\sigma^k(i)}^l)^l = z_{\sigma^k(i)}^{kl} = z_i^{k+1},
\]
so the result is true for \(k + 1\) and, by induction, for all \(k \in \mathbb{N}^*\). In particular, it is true for \(k = r!\), the cardinal of the symmetric group \(\Sigma_r\) and hence \(z_i^{r^r} = z_i^m\). From this we deduce that \(z_i\) is root of unity.

**Corollary 11.4** \(x\) is a root of unity in a number field \(K\) if and only if \(x \in O_K\) and \(|x^{(i)}| = 1\), for every conjugate of \(x\).

**Proof** Let \(x\) be a root of unity. We have already seen that a root of unity must lie in \(O_K\). There exists a positive integer \(m\) such that \(x^m = 1\). As the conjugates \(x^{(i)}\) of \(x\) are also roots of the polynomial \(f(X) = -1 + X^m\), we must have \(|x^{(i)}|^m = 1\), which implies that \(|x^{(i)}| = 1\).

Now suppose that \(x \in O_K\) and \(|x^{(i)}| = 1\), for all conjugates \(x^{(i)}\) of \(x\). The conjugates are the roots of the minimal polynomial \(m(x, Q)\), so by Proposition 11.9 they are roots of unity; in particular, \(x\) is a root of unity.

**Exercise 11.6** Let \(K\) be a number field, \(x \in K\) and \(m \in \mathbb{N}^*\). Show that the conjugates of \(x^m\) are \(m\)th powers of the conjugates of \(x\).

If \(p\) is an odd prime, \(\zeta = e^{2\pi i/p}\) and \(K = Q(\zeta)\), then we can be more precise with respect to the roots of unity of \(K\).

**Theorem 11.11** If \(p\) is an odd prime and \(\zeta = e^{2\pi i/p}\), then the roots of unity in \(K = Q(\zeta)\) are of the form \(\pm \zeta^j\), with \(1 \leq j \leq p\).

**Proof** From Theorem 11.10 we know that the roots of unity form a finite cyclic group \(C\). If \(|C| = m\), then there is a generator \(z = e^{2\pi i/m}\) of \(C\). (It is sufficient to take \(l\) coprime to \(m\).) If \(x \in C\), then \(-x \in C\), because \(x^k = 1\) implies that \((-x)^k = 1\), hence \(-\zeta \in C\) and so there exists \(s \in \mathbb{N}^*\) such that \(z^s = -\zeta\), i.e., \(e^{2\pi is/m} = e^{2\pi i/p + \pi i}\). From this we deduce that there exists \(k \in \mathbb{Z}\) such that
\[
\frac{2\pi is}{m} = \frac{2\pi i}{p} + \pi i + 2k\pi i \implies 2sp = m(2 + p(2k + 1)) \implies 2p|m,
\]
because neither 2 nor \(p\) divides \(2 + p(2k + 1)\).

As \(z\) is a generator of \(C\), \(\zeta\) is a power of \(z\) and so \(Q(\zeta) \subset Q(z)\). However, \(z \in Q(\zeta)\) and so we also have \(Q(z) \subset Q(\zeta)\) and it follows that \(Q(\zeta) = Q(z)\). This being the case, we have
\[
\phi(m) = [Q(z) : Q] = [Q(\zeta) : Q] = \phi(p) = p - 1,
\]
122
where \( \phi \) is Euler’s totient function. We may write \( m = 2^\alpha p^\beta m', \) with \( \alpha \geq 1, \beta \geq 1 \) and \( p \nmid m', \) and
\[
p - 1 = \phi(m) = 2^{\alpha - 1}p^{\beta - 1}(p - 1)\phi(m') \implies 1 = 2^{\alpha - 1}p^{\beta - 1}\phi(m').
\]
Therefore \( \alpha = \beta = \phi(m') = 1. \) As \( m' \neq 2, \) we have \( m' = 1 \) and so \( m = 2p. \) Thus the cardinal of \( C \) is \( 2p. \) Since the elements \( \pm \zeta^i, \) with \( 1 \leq i \leq p, \) belong to \( C \) and are distinct, these are the roots of unity in \( K. \) \( \square \)

**Exercise 11.7** Show that a number field of odd degree has just two roots of unity.

### 11.4 Composita of number fields

We recall that, if \( K \) and \( L \) are subfields of a field \( E, \) then the compositum of \( K \) and \( L \) in \( E, \) which we write \( KL, \) is the smallest subfield of \( E \) containing both \( K \) and \( L. \) In this section we consider the case where \( K \) and \( L \) are number fields (considered as subfields of \( C. \) ) We will be particularly interested in the number ring \( O_{KL} \) of \( KL. \)

Let \( K \) and \( L \) be number fields and \( O_K, O_L \) the associated number rings. From Proposition 6.4 we know that \([KL : Q] \leq [K : Q][L : Q],\) with equality when \([K : Q] \) and \([L : Q] \) are coprime, or said otherwise, when \( K \) and \( L \) are linearly disjoint. We set \( R = O_K, S = O_L \) and
\[
RS = \{ \sum_{i \in I} r_is_i : r_i \in R, s_i \in S, |I| < \infty \}
\]

\( RS \) is clearly a subring of \( O_{KL}. \) The following result provides a sufficient condition for equality.

**Theorem 11.12** Let \( K \) and \( L \) be linearly disjoint number fields and \( d = \gcd(\text{disc}(R), \text{disc}(S)). \) Then \( O_{KL} \subset \frac{1}{d}RS. \) Thus, if \( d = 1, \) then \( O_{KL} = RS. \)

**Proof** Let \( m = [K : Q], n = [L : Q] \) and \( \{\alpha_1, \ldots, \alpha_m\}, \{\beta_1, \ldots, \beta_n\} \) integral bases respectively of \( R \) and \( S. \) These bases are bases over \( Q \) of respectively \( K \) and \( L. \) As \( K \) and \( L \) are linearly disjoint over \( Q, \) the set
\[
A = \{\alpha_i\beta_j : 1 \leq i \leq m, 1 \leq j \leq n\}
\]
is a basis of \( KL \) over \( Q. \) (See the discussion on linear disjointness after Proposition 6.4.) Hence, if \( x \in O_{KL}, \) then there exist rational numbers \( q_{ij}, \) for \( 1 \leq i \leq m \) and \( 1 \leq j \leq n, \) such that
\[
x = \sum_{i,j} q_{ij}\alpha_i\beta_j.
\]

We aim to show that \( dq_{ij} \in Z, \) for all \( i \) and \( j. \) If this is the case, then we may write
\[
x = \frac{1}{d} \sum_{i,j} (dq_{ij})\alpha_i\beta_j \in \frac{1}{d}RS
\]
and it follows that \( O_{KL} \subset \frac{1}{d}RS. \) To establish that \( dq_{ij} \in Z \) it is sufficient to show that \( \text{disc}(R)q_{ij} \in Z. \) If we can do this, then with an analogous argument we may show that \( \text{disc}(S)q_{ij} \in Z. \) As there exist \( u, v \in Z \) such that \( d = u\text{disc}(R) + v\text{disc}(S), \) \( dq_{ij} \in Z. \)
From Corollary 3.2 we know that there are exactly \([K : \mathbb{Q}]\) \(\mathbb{Q}\)-monomorphisms of \(K\) into \(\mathbb{C}\). Let \(\sigma\) be such a monomorphism. Theorem 3.2 ensures that there are exactly \([KL : K]\) monomorphic extensions \(\tilde{\sigma}\) of \(\sigma\) into \(\mathbb{C}\). Restricting the \(\tilde{\sigma}\) to \(L\), we obtain \([KL : K]\) distinct monomorphisms \(\sigma'\) from \(L\) into \(\mathbb{C}\). (If two such restrictions \(\sigma'_1\) and \(\sigma'_2\) are equal, then the corresponding mappings \(\tilde{\sigma}_1\) and \(\tilde{\sigma}_2\) are equal on \(K\) and \(L\) and consequently on \(KL\), contradicting the fact that \(\tilde{\sigma}_1\) and \(\tilde{\sigma}_2\) are distinct.) As \(K\) and \(L\) are linearly disjoint \([KL : K] = [L : \mathbb{Q}]\), therefore the considered restrictions are the \(\mathbb{Q}\)-monomorphisms from \(L\) into \(\mathbb{C}\). In particular, one such restriction is the identity on \(L\). Consequently, for the corresponding \(\tilde{\sigma}\), we have

\[
\tilde{\sigma}(x) = \sum_{i=1}^{m} \sum_{j=1}^{n} \tilde{\sigma}(q_{ij})\tilde{\sigma}(\alpha_i)\tilde{\sigma}(\beta_j) = \sum_{i=1}^{m} x_i\sigma(\alpha_i),
\]

where \(x_i = \sum_{j=1}^{n} q_{ij}\beta_j\). We may use the same procedure for each of the \([K : \mathbb{Q}]\) \(\mathbb{Q}\)-monomorphisms \(\sigma_1, \ldots, \sigma_m\) from \(K\) into \(\mathbb{C}\) and obtain the corresponding extensions \(\tilde{\sigma}_1, \ldots, \tilde{\sigma}_m\). In this way we obtain a system of \(m\) equations in \(m\) unknowns, the \(x_i\):

\[
\begin{align*}
\tilde{\sigma}_1(x) &= \sigma_1(\alpha_1)x_1 + \cdots + \sigma_1(\alpha_m)x_m \\
\tilde{\sigma}_2(x) &= \sigma_2(\alpha_1)x_1 + \cdots + \sigma_2(\alpha_m)x_m \\
&\vdots \\
\tilde{\sigma}_m(x) &= \sigma_m(\alpha_1)x_1 + \cdots + \sigma_m(\alpha_m)x_m.
\end{align*}
\]

Applying Cramer’s rule we find the expression for the \(x_i\):

\[
x_i = \frac{\nu_i}{\delta},
\]

where \(\delta\) is the determinant of the matrix \((\sigma_i(\alpha_j))\) and \(\nu_i\) the determinant of the matrix obtained from the previous matrix by replacing the \(i\)th column by that composed of the elements \(\tilde{\sigma}_i(x)\). (As the \(\alpha_j\) are independent, \(\delta \neq 0\), from Proposition 10.8.) As \(x \in O_{KL}\), \(x\) is an algebraic integer and so \(\tilde{\sigma}_i(x)\) is an algebraic integer; also, the \(\alpha_j\) belong to \(R\) and so are algebraic integers, which implies that the \(\sigma_i(\alpha_j)\) are algebraic integers. It follows that \(\delta\) and the \(\nu_i\) are algebraic integers. Now, we have

\[
\delta^2 x_i = \delta \nu_i = u_i \in O_{KL}.
\]

However, \(\delta^2 = \text{disc}(R) \in \mathbb{Z}\), so

\[
u_i = \text{disc}(R)x_i = \sum_{i=1}^{m} \text{disc}(R)q_{ij}\beta_j.
\]

Hence, \(u_i\) is an algebraic integer in \(R\) and its coefficients in the basis \((\beta_j)\) are \(\text{disc}(R)q_{ij}\). It follows that the elements \(\text{disc}(R)q_{ij}\) are integers. This finishes the proof. \(\square\)

We now consider the relation between the discriminants of the number rings \(R\) and \(S\) and the discriminant of \(O_{KL}\).

**Theorem 11.13** Let \(K\) and \(L\) be linearly disjoint number fields whose number rings have co-prime discriminants. Then

\[
\text{disc}(O_{KL}) = \text{disc}(R)^{|L:Q|} \text{disc}(S)^{|K:Q|}.
\]

124
From Theorem H.1, we have Lemma 11.4 If $\mathbb{Q}$ is a primitive $n$th root of unity, then the set $A = \{1, \zeta, \ldots, \zeta^{\phi(n)-1}\}$ is a basis of $\mathbb{Q}(\zeta)$ over $\mathbb{Q}$. ($\phi$ is the Euler totient function.)
PROOF In the proof of Theorem 7.7 we observed that \( \mathbb{Q}(\zeta) : \mathbb{Q} = \phi(n) \). As \( |A| = \phi(n) \), we only need to show that the set \( A \) is linearly independent over \( \mathbb{Q} \). If

\[
\lambda_0 + \lambda_1 \zeta + \cdots + \lambda_{\phi(n) - 1} \zeta^{\phi(n) - 1} = 0,
\]

where the \( \lambda_i \) are elements of \( \mathbb{Q} \), which are not all zero, then \( \zeta \) is a root of a nonzero polynomial \( f \in \mathbb{Q}[X] \), whose degree is less than \( \phi(n) \). However, the minimal polynomial of \( \zeta \) over \( \mathbb{Q} \) is \( \Phi_n \), whose degree is \( \phi(n) \), so we have a contradiction. Hence \( A \) is a basis of \( \mathbb{Q}(\zeta) \) over \( \mathbb{Q} \). \( \square \)

**Proposition 11.10** If \( p \) is a prime number, \( r \in \mathbb{N}^* \) and \( \zeta \) a primitive \( p^r \)-th root of unity, then

\[
\mathbb{O}_{\mathbb{Q}(\zeta)} = \mathbb{Z}[\zeta].
\]

PROOF From Lemma 11.4 the set \( A = \{1, \zeta, \ldots, \zeta^{\phi(p^r) - 1}\} \) is a basis of \( \mathbb{Q}(\zeta) \) over \( \mathbb{Q} \). Also, the elements of this set belong to \( \mathbb{O}_{\mathbb{Q}(\zeta)} \), because \( \zeta \) is an algebraic integer. The proof of Theorem 11.8 shows that

\[
d\mathbb{O}_{\mathbb{Q}(\zeta)} \subset \mathbb{Z} \oplus \mathbb{Z}[\zeta] \oplus \cdots \oplus \mathbb{Z}[\zeta^{\phi(p^r) - 1}],
\]

where \( d = \text{disc}_{\mathbb{Q}(\zeta)}/(1, \zeta, \ldots, \zeta^{\phi(p^r) - 1}) \). Thus, \( \mathbb{O}_{\mathbb{Q}(\zeta)} \subset \mathbb{Z}[\zeta] \). Moreover, from Corollary 10.6, \( d \) is a power of \( p \) (up to sign). Therefore there exists \( m \in \mathbb{N}^* \) such that \( p^m \mathbb{O}_{\mathbb{Q}(\zeta)} \subset \mathbb{Z}[\zeta] \).

If

\[
\mathbb{Z}[\zeta] \cap p\mathbb{O}_{\mathbb{Q}(\zeta)} = p\mathbb{Z}[\zeta],
\]

then, as \( p^m \mathbb{O}_{\mathbb{Q}(\zeta)} \subset \mathbb{Z}[\zeta] \), we have

\[
p^m \mathbb{O}_{\mathbb{Q}(\zeta)} \subset \mathbb{Z}[\zeta] \cap p\mathbb{O}_{\mathbb{Q}(\zeta)} \subset p\mathbb{Z}[\zeta] \implies p^{m-1} \mathbb{O}_{\mathbb{Q}(\zeta)} \subset \mathbb{Z}[\zeta].
\]

If \( m = 1 \), then we immediately have \( \mathbb{O}_{\mathbb{Q}(\zeta)} \subset \mathbb{Z}[\zeta] \); if not, then it is sufficient to iterate the process to obtain the same inclusion. As \( \mathbb{Z}[\zeta] \) is clearly contained in \( \mathbb{O}_{\mathbb{Q}(\zeta)} \), we only need to establish the identity (11.1) to finish the proof. This is what we now do.

Our first step is to show that

\[
\mathbb{O}_{\mathbb{Q}(\zeta)} p = \mathbb{O}_{\mathbb{Q}(\zeta)} (-\zeta + 1)^{\phi(p^r)}
\]

(11.2)

To begin,

\[
\Phi_{p^r}(X) = \prod_{1 \leq i < p^r, (i, p) = 1} (-\zeta^i + X) \implies \Phi_{p^r}(1) = \prod_{1 \leq i < p^r, (i, p) = 1} (-\zeta^i + 1).
\]

However, from Exercise 7.4, we know that

\[
\Phi_{p^r}(X) = \Phi_p(X^{p^{-1}})
\]

so

\[
p = \Phi_{p^r}(1) = \prod_{1 \leq i < p^r, (i, p) = 1} (-\zeta^i + 1).
\]

Next we observe that the elements \(-\zeta^i + 1 \overline{\zeta + 1}\), with \( 1 \leq i < p^r \) and \( (i, p) = 1 \), are units in \( \mathbb{O}_{\mathbb{Q}(\zeta)} \).

We have

\[
-\zeta^i + 1 \overline{\zeta + 1} = 1 + \zeta + \cdots + \zeta^{i-1} \in \mathbb{O}_{\mathbb{Q}(\zeta)}.
\]

126
As \( \zeta^i \) is a primitive \( p^r \)th root of unity, there exists \( s \in \mathbb{N}^* \) such that \( \zeta = \zeta^{is} \), hence

\[
\frac{-\zeta + 1}{-\zeta^i + 1} = \frac{-\zeta^{is} + 1}{-\zeta^i + 1} = 1 + \zeta^i + \cdots + \zeta^{(s-1)i} \in O_{Q(\zeta)},
\]

so \( \frac{-\zeta^i + 1}{\zeta + 1} \) is a unit in \( O_{Q(\zeta)} \).

We may write

\[
-\zeta^i + 1 = \frac{-\zeta^i + 1}{\zeta + 1} \cdot (-\zeta + 1) = u_i(-\zeta + 1),
\]

so

\[
p = \prod_{1 \leq i < p^r, (i, p) = 1} u_i(-\zeta + 1) = u(-\zeta + 1)^{\phi(p^r)},
\]

where \( u \) is a unit in \( O_{Q(\zeta)} \). As \( p \) and \( (-\zeta + 1)^{\phi(p^r)} \) are associates in \( O_{Q(\zeta)} \), they generate the same ideal, i.e.,

\[
O_{Q(\zeta)}p = O_{Q(\zeta)}(-\zeta + 1)^{\phi(p^r)},
\]

as asserted.

Our second step is to show that

\[
O_{Q(\zeta)}(-\zeta + 1) \cap \mathbb{Z} = \mathbb{Z}p. \tag{11.3}
\]

From the identity (11.2) we obtain \( p \in (-\zeta + 1)O_{Q(\zeta)} \), and so \( p \mathbb{Z} \subseteq (-\zeta + 1)O_{Q(\zeta)} \cap \mathbb{Z} \). Now the reverse inclusion. If \( x \in (-\zeta + 1)O_{Q(\zeta)} \), then \( x = y(-\zeta + 1) \), with \( y \in O_{Q(\zeta)} \), and

\[
N_{Q(\zeta)/Q}(x) = N_{Q(\zeta)/Q}(y)N_{Q(\zeta)/Q}(-\zeta + 1).
\]

As \( y \in O_{Q(\zeta)} \), \( N_{Q(\zeta)/Q}(y) \in \mathbb{Z} \) (Exercise 11.1). Also, from Corollary 10.1,

\[
N_{Q(\zeta)/Q}(-\zeta + 1) = \prod_{1 \leq i < p^r, (i, p) = 1} (-\zeta^i + 1) = p,
\]

because \( Q(\zeta) \) is the splitting field of the polynomial \( \Phi_{p^r}(1 - X) \), whose roots are \( -\zeta^i + 1 \), with \( 1 \leq i < p^r \) and \( (i, p) = 1 \). Finally, as \( x \in \mathbb{Z} \), \( N_{Q(\zeta)/Q}(x) = x^{\phi(p^r)} \), so \( p|x \), i.e., \( x \in p\mathbb{Z} \). This concludes the second step. We have

\[
O_{Q(\zeta)}(-\zeta + 1) \cap \mathbb{Z} = \mathbb{Z}p,
\]

as required.

We are now in a position to prove the identity (11.1). There is no difficulty in seeing that

\[
\mathbb{Z}[\zeta]p \subseteq \mathbb{Z}[\zeta] \cap O_{Q(\zeta)}p.
\]

For the reverse inclusion, let us take \( x \in \mathbb{Z}[\zeta] \cap O_{Q(\zeta)}p \). Using the fact that \( A = \{1, \zeta, \ldots, \zeta^{\phi(p^r) - 1}\} \) is a basis of \( Q(\zeta) \) over \( Q \), we see that the set \( B = \{1, -\zeta + 1, \ldots, (-\zeta + 1)^{\phi(p^r) - 1}\} \) is also a basis of \( Q(\zeta) \) over \( Q \). The set \( B \) is included in \( \mathbb{Z}[\zeta] \) and is independant over \( \mathbb{Z} \), because it is independant over \( Q \). As \( A \) is a generating set of \( \mathbb{Z}[\zeta] \) and the elements of \( A \) can be written as linear combinations of those of \( B \) with coefficients in \( \mathbb{Z} \), \( B \) is a generating set of \( \mathbb{Z}[\zeta] \). Thus \( B \) is a basis of the \( \mathbb{Z} \)-module \( \mathbb{Z}[\zeta] \). Therefore there exist integers \( c_0, c_1, \ldots, c_{\phi(p^r) - 1} \) such that

\[
x = c_0 + c_1(-\zeta + 1) + \cdots + c_{\phi(p^r) - 1}(-\zeta + 1)^{\phi(p^r) - 1}.
\]
Moreover, from the identity (11.2), there exists \( v \in \text{O}_{\mathbb{Q}(\zeta)} \) such that \( x = (-\zeta + 1)^{\phi(p^r)}v \). Thus \( c_0 \in \text{O}_{\mathbb{Q}(\zeta)}(-\zeta + 1) \cap \mathbb{Z} \), which from the identity (11.3) is equal to \( p\mathbb{Z} \). Therefore \( c_0 \in p\mathbb{Z} \). Using the identity (11.2) again, we see that \( p \in (-\zeta + 1)^{\phi(p^r)}\text{O}_{\mathbb{Q}(\zeta)} \), hence \( x - c_0 \in (-\zeta + 1)^{\phi(p^r)}\text{O}_{\mathbb{Q}(\zeta)} \).

We may write \( x - c_0 = (-\zeta + 1)x_1 \), where

\[
x_1 = c_1 + c_2(-\zeta + 1) + \cdots + c_{\phi(p^r) - 1}(-\zeta + 1)^{\phi(p^r) - 2} \in (-\zeta + 1)^{\phi(p^r) - 1}\text{O}_{\mathbb{Q}(\zeta)}.
\]

As for \( c_0 \), we find that \( c_1 \in p\mathbb{Z} \). Continuing in the same way, we obtain that \( c_i \in p\mathbb{Z} \), for all \( i \) and so \( x \in p\mathbb{Z} \). This ends the proof.

We have shown that \( \text{O}_{\mathbb{Q}(\zeta)} = \mathbb{Z}[\zeta] \) when \( \zeta \) is a \( p^r \)th root of unity. We now turn to the general case. Here Theorem 11.12 plays an important role. We will need a preliminary result.

**Lemma 11.5** If \( \zeta \) is a primitive \( n \)th root of unity, then the discriminant \( \text{disc}_{\mathbb{Q}(\zeta)}/\mathbb{Q}(1, \zeta, \dotsc, \zeta^{\phi(n)-1}) \) divides \( n^{\phi(n)} \).

**Proof** From Proposition 10.9

\[
\text{disc}_{\mathbb{Q}(\zeta)}/\mathbb{Q}(1, \zeta, \dotsc, \zeta^{\phi(n)-1}) = (-1)^{\frac{\phi(n)(\phi(n)-1)}{2}}N_{\mathbb{Q}(\zeta)}/\mathbb{Q}(\Phi_n' \zeta)).
\]

Since \( \Phi_n \) is the minimal polynomial of \( \zeta \) over \( \mathbb{Q} \) and \( \zeta^n = 1 \), there exists \( g \in \mathbb{Q}[X] \) such that \( -1 + X^n = \Phi_n(X)g(X) \).

As \( \Phi_n \) is monic, \( g \) is also monic and Lemma 11.1 ensures that \( g \in \mathbb{Z}[X] \). Differentiating both sides of the previous equation and evaluating at \( \zeta \) leads to

\[
n\zeta^{n-1} = \Phi_n' \zeta g(\zeta) \implies n = \zeta \Phi_n' \zeta g(\zeta).
\]

Taking the norm on both sides, we obtain

\[
n^{\phi(n)} = N_{\mathbb{Q}(\zeta)}/\mathbb{Q}(\Phi_n' \zeta))N_{\mathbb{Q}(\zeta)}/\mathbb{Q}(\zeta g(\zeta)) = N_{\mathbb{Q}(\zeta)}/\mathbb{Q}(\Phi_n' \zeta)).N_{\mathbb{Q}(\zeta)}/\mathbb{Q}(\zeta g(\zeta)) = N_{\mathbb{Q}(\zeta)}/\mathbb{Q}(\Phi_n' \zeta)),
\]

However, \( \Phi_n' \zeta \) and \( \zeta g(\zeta) \) are elements of \( \mathbb{Z}[\zeta] \), which is included in \( \text{O}_{\mathbb{Q}(\zeta)} \). Applying Exercise 11.1 we obtain the result.

**Theorem 11.14** If \( \zeta \) is a primitive \( n \)th root of unity, then

\[
\text{O}_{\mathbb{Q}(\zeta)} = \mathbb{Z}[\zeta].
\]

**Proof** We will use an induction on \( s \), the number of prime factors in the decomposition of \( n \). For \( s = 1 \), we have already proved the result, so we consider the induction step. Let us suppose that the result is true up to \( s - 1 \). We now consider the case \( s \). We have

\[
n = p_1^{s_1}p_2^{s_2} \cdots p_s^{s_s} = m_1m_2,
\]

where \( m_1 = p_1^{s_1} \) and \( m_2 = p_2^{s_2} \cdots p_s^{s_s} \). As \( m_1 \) and \( m_2 \) are coprime, from Proposition 7.6

\[
\mathbb{Q}(\zeta_m_1) \mathbb{Q}(\zeta_m_2) = \mathbb{Q}(\zeta_n),
\]

where \( \zeta_n \) is a primitive \( n \)th root of unity. From Proposition 11.10 (or the induction hypothesis),

\[
\text{disc}(\text{O}_{\mathbb{Q}(\zeta м_1)}) = \text{disc}_{\mathbb{Q}(\zeta м_1)}(1, \zeta м_1, \dotsc, \zeta^{\phi(m_1)-1}),
\]

128
because \( \{1, \zeta_{m_1}, \ldots, \zeta_{m_1}^{\phi(m_1) - 1}\} \) is an integral basis of \( \mathcal{O}_{\mathbb{Q}(\zeta_{m_1})} \). Also, by the induction hypothesis,
\[
\text{disc}(\mathcal{O}_{\mathbb{Q}(\zeta_{m_2})}) = \text{disc}_{\mathbb{Q}(\zeta_{m_2})/\mathbb{Q}}(1, \zeta_{m_2}, \ldots, \zeta_{m_2}^{\phi(m_2) - 1}),
\]
because \( \{1, \zeta_{m_2}, \ldots, \zeta_{m_2}^{\phi(m_2) - 1}\} \) is an integral basis of \( \mathcal{O}_{\mathbb{Q}(\zeta_{m_2})} \). From Lemma 11.5, as \( m_1^{\phi(m_1)} \) and \( m_2^{\phi(m_2)} \) are coprime, so are the discriminants \( \text{disc}(\mathcal{O}_{\mathbb{Q}(\zeta_{m_1})}) \) and \( \text{disc}(\mathcal{O}_{\mathbb{Q}(\zeta_{m_2})}) \). In addition, \( \mathbb{Q}(\zeta_{m_1}) \) and \( \mathbb{Q}(\zeta_{m_2}) \) are linearly disjoint over \( \mathbb{Q} \), because \( \phi(m_1m_2) = \phi(m_1)\phi(m_2) \). Applying Theorem 11.12 and the induction hypothesis, we obtain
\[
\mathcal{O}_{\mathbb{Q}(\zeta_n)} = \mathcal{O}_{\mathbb{Q}(\zeta_{m_1})}\mathcal{O}_{\mathbb{Q}(\zeta_{m_2})} = \mathbb{Z}[\zeta_{m_1}]\mathbb{Z}[\zeta_{m_2}],
\]
Given that \( \zeta_n^{m_2} \) is a primitive \( m_1 \)th root of unity, \( \zeta_{m_1} \in \mathbb{Z}[\zeta_n] \). In the same way, \( \zeta_{m_2} \in \mathbb{Z}[\zeta_n] \), so \( \mathbb{Z}[\zeta_{m_1}]\mathbb{Z}[\zeta_{m_2}] \subseteq \mathbb{Z}[\zeta_n] \). Moreover, as \( m_1 \) and \( m_2 \) are coprime, there exist integers \( u \) and \( v \) such that \( m_1u + m_2v = 1 \). Thus,
\[
\zeta_n = (\zeta_n^{m_2})^r(\zeta_n^{m_1})^u \in \mathbb{Z}[\zeta_{m_1}]\mathbb{Z}[\zeta_{m_2}] \implies \mathbb{Z}[\zeta_n] \subseteq \mathbb{Z}[\zeta_{m_1}]\mathbb{Z}[\zeta_{m_2}],
\]
therefore
\[
\mathbb{Z}[\zeta_n] = \mathbb{Z}[\zeta_{m_1}]\mathbb{Z}[\zeta_{m_2}] = \mathcal{O}_{\mathbb{Q}(\zeta_n)},
\]
as required. \( \square \)

We now turn to the discriminant of a cyclotomic number ring \( \mathcal{O}_{\mathbb{Q}(\zeta)} \). Proposition 10.9 ensures that
\[
\Delta(\Phi_n) = \text{disc}\mathbb{Q}(\zeta)/\mathbb{Q}(1, \zeta, \ldots, \zeta^{\phi(n) - 1}) = \text{disc}(\mathcal{O}_{\mathbb{Q}(\zeta)}),
\]
so, in finding \( \text{disc}(\mathcal{O}_{\mathbb{Q}(\zeta)}) \), we find \( \Delta(\Phi_n) \), or vice-versa. In fact, we have already found \( \Delta(\Phi_{p^r}) \), where \( p \) is a prime number and \( r \) a positive integer (Corollary 10.6). We now generalize this result. Theorem 11.13 will play an important role.

**Theorem 11.15** Let \( \zeta \) be a primitive \( n \)th root of unity. Then
\[
\Delta(\Phi_n) = \text{disc}(\mathcal{O}_{\mathbb{Q}(\zeta)}) = \frac{(-1)^c n^{\phi(n)}}{\prod_{p\mid n} p^{\frac{\phi(n)}{\phi(p)}}},
\]
where \( c_n = \frac{\phi(n)}{2} \), if \( n \neq 2 \) and \( c_2 = 0 \).

**Proof** We will use an induction on \( s \), the number of prime factors in \( n \). First, if \( n \) has a single prime factor \( p \), the \( n = p^r \), for some \( r \in \mathbb{N}^\ast \). In Corollary 10.6 we found the expression
\[
\Delta(\Phi_{p^r}) = (-1)^c p^{r-1}(r-1)^{-1},
\]
where \( c = \frac{\phi(p^r)}{2} \), if \( p \) is odd or \( r > 1 \), and \( c = 0 \) otherwise. However,
\[
(p^r)^{\phi(p^r)} = (p^r)^{r-1}(p-1) = p^{r-1}(p-1)
\]
and
\[
\prod_{p \mid p^r} p^{\frac{\phi(p^r)}{\phi(p)}} = \prod_{p \mid p^r} p^{r-1} = p^{r-1}.
\]
Hence, if \( n = p^r \), i.e., \( s = 1 \), then the expression for \( \Delta(\Phi_n) \) given in the statement of the theorem is correct.

129
Let us now suppose that \( s \geq 2 \) and that the result is true up to \( s - 1 \). We have

\[
n = p_1^{α_1} p_2^{α_2} \cdots p_s^{α_s} = m_1 m_2,
\]

where \( m_1 = p_1^{α_1} \) and \( m_2 = p_2^{α_2} \cdots p_s^{α_s} \). As in the proof of Theorem 11.14, we find that \( \text{disc}(O_{m_1}) \) and \( \text{disc}(O_{m_2}) \) are coprime. Using the induction hypothesis and Theorem 11.13 we obtain

\[
\text{disc}(O_{\mathbb{Q}(\zeta)}) = \left( \frac{(-1)^{c_{m_1} φ(m_1)}}{\prod_{p|m_1} b_{p^{\frac{1}{2}}}} \right) \times \left( \frac{(-1)^{c_{m_2} φ(m_2)} m_2^{\frac{1}{2}}}{\prod_{p|m_2} p^{\frac{1}{m_2} \phi(n)}} \right).
\]

To finish the induction step we only need to consider the term \((-1)^{c_{m_1} φ(m_2) + c_{m_2} φ(m_1)}\). If all the primes in \( n \) are odd, then

\[
c_{m_1} φ(m_2) = c_{m_2} φ(m_1) \quad \implies \quad (-1)^{c_{m_1} φ(m_2) + c_{m_2} φ(m_1)} = (-1)^{2d(n) \frac{n}{2}} = 1.
\]

If \( p_1 = 2 \) and \( α_1 \geq 2 \), then we have an analogous argument. To finish, suppose that \( p_1 = 2 \) and \( α_1 = 1 \). Then

\[
c_{m_1} φ(m_2) + c_{m_2} φ(m_1) = \frac{φ(m_1) φ(m_2)}{2} = \frac{φ(n)}{2} = c_n,
\]

because \( n \) has at least two factors. This ends the induction step. \( \square \)

We have seen in Theorem 11.14 that if \( α \) is a primitive \( n \)th root of unity, then the number ring of \( \mathbb{Q}(α) \) is \( \mathbb{Z}[α] \). In Theorem 11.6 we observed a similar phenomenon for the case where \( α \) is the square root of a square-free integer \( d = 2, 3 \pmod{4} \). In the next proposition we give another criterion.

**Proposition 11.11** If \( K \) is a number field, then there is an algebraic integer \( s \) such that \( K = \mathbb{Q}(s) \). If the discriminant of the minimal polynomial \( m(s, \mathbb{Q}) \) is a square-free integer, then \( O_K = \mathbb{Z}[s] \).

**Proof** The primitive element theorem (Theorem 3.4) ensures that for any number field \( K \), there is an element \( t \in K \) such that \( K = \mathbb{Q}(t) \). Since \( t \) is an algebraic number, because \( K \) is a finite extension of \( \mathbb{Q} \), Lemma 11.2 ensures that \( t = \frac{1}{s} \), where \( s \) is an algebraic integer and \( k \) a positive integer. Consequently, \( K = \mathbb{Q}(s) \), for some algebraic integer \( s \).

As \( s \in O_K \), we must have \( \mathbb{Z}[s] \subset O_K \). We now aim to show that the condition on the discriminant of the minimal polynomial \( m(s, \mathbb{Q}) \) ensures the reverse inclusion. From Theorem 11.8 we obtain that the number ring \( O_K \) has an integral basis \( \{x_0, \ldots, x_{n-1}\} \), where \( n = [K : \mathbb{Q}] \). Since \( s \in O_K \), there is a matrix \( M \in \mathcal{M}_n(\mathbb{Z}) \) such that

\[
\begin{pmatrix}
1 \\
s \\
\vdots \\
s^{n-1}
\end{pmatrix}
= M
\begin{pmatrix}
x_0 \\
x_1 \\
\vdots \\
x_{n-1}
\end{pmatrix}.
\]

Let \( σ_1, \ldots, σ_n \) be the \( \mathbb{Q} \)-monomorphisms from \( K \) into \( \mathbb{C} \). For \( j = 1, \ldots, n \), we have

\[
\begin{pmatrix}
σ_j(1) \\
σ_j(s) \\
\vdots \\
σ_j(s^{n-1})
\end{pmatrix}
= M
\begin{pmatrix}
σ_j(x_0) \\
σ_j(x_1) \\
\vdots \\
σ_j(x_{n-1})
\end{pmatrix}.
\]

130
We may write this expression in matrix form:

\[
(\sigma_j(s^i)) = M(\sigma_j(x_i)).
\]

Taking determinants and squaring we obtain

\[
\text{disc}_{K/\mathbb{Q}}(1,s,\ldots,s^{n-1}) = (\det M)^2 \text{disc}_{K/\mathbb{Q}}(x_0,x_1,\ldots,x_{n-1}).
\]

Now Proposition 10.9 ensures that \(\text{disc}_{K/\mathbb{Q}}(1,s,\ldots,s^{n-1})\) is the discriminant of the minimal polynomial \(m(s, \mathbb{Q})\), which, by hypothesis, is a square-free integer. In addition, the discriminant \(\text{disc}_{K/\mathbb{Q}}(x_0,x_1,\ldots,x_{n-1})\) belongs to \(\mathbb{Z}\). (Clearly, \(\text{disc}_{K/\mathbb{Q}}(x_0,x_1,\ldots,x_{n-1}) \in \mathbb{Q}\); it is integral over \(\mathbb{Z}\), because each \(x_i\) is integral over \(\mathbb{Z}\).) Since \(\det M \in \mathbb{Z}\), because \(M \in M_n(\mathbb{Z})\), we have \(\det M = \pm 1\), and it follows that the entries of \(M^{-1}\) are integers. As

\[
\begin{pmatrix}
  x_0 \\
  x_1 \\
  \vdots \\
  x_{n-1}
\end{pmatrix} = M^{-1}
\begin{pmatrix}
  1 \\
  s \\
  \vdots \\
  s^{n-1}
\end{pmatrix},
\]

and the \(x_i\) generate \(O_K\), the \(s^i\) also generate \(O_K\) over \(\mathbb{Z}\), which proves that \(O_K \subset \mathbb{Z}[s]\), as required, and so \(O_K = \mathbb{Z}[s]\).

As the set \(\{1,s,\ldots,s^{n-1}\}\) is independent over \(\mathbb{Z}\), it is an integral basis of \(O_K\).

\[\square\]

Example Let \(K = \mathbb{Q}(\alpha)\), where \(-1 - \alpha + \alpha^3 = 0\). The minimal polynomial of \(\alpha\) over \(\mathbb{Q}\) is \(f(X) = -1 - X + X^3\), whose discriminant is \(-23\). As \(-23\) is square-free, we have \(O_K = \mathbb{Z}[\alpha]\).

Remark We should notice that, if the discriminant of the minimal polynomial of \(\alpha\) is not square-free, then \(O_K\) may or may not be equal to \(\mathbb{Z}[\alpha]\); it is sufficient to consider the case where \(d\) is square-free and \(\alpha = \sqrt{d}\).

### 11.5 Ideals in number rings

In this section we concentrate on the properties of ideals in number rings. Our first result concerns the factor ring \(O_K/I\) for an nonzero ideal. We recall that \(n\) denotes the dimension of \(K\) over \(\mathbb{Q}\).

**Proposition 11.12** If \(I\) is a nonzero ideal in a number ring \(O_K\), then the factor ring \(O_K/I\) is finite.

**Proof** Let \(I\) be a nonzero ideal in the number ring \(O_K\) and \(\alpha\) a nonzero element of \(I\). We set \(m = N_{K/\mathbb{Q}}(\alpha)\). As \(\alpha \in O_K\), \(\alpha\) is an algebraic integer and so \(m \in \mathbb{Z}\). From the definition of the norm, \(m \neq 0\). We claim that \(m \in I\): From Proposition 10.2, \(m = \alpha \beta\), where \(\beta\) is a product of conjugates of \(\alpha\) (in \(C\)); as \(m, \alpha \in K, \beta = \frac{m}{\alpha} \in K\). As a conjugate of an algebraic integer is also an algebraic integer, \(\beta\) is an algebraic integer. Thus \(\beta \in O_K\) and it follows that \(m \in I\), as claimed.

As \(m \in I\), the principal ideal \((m)\) is included in \(I\). Since the rank of the free abelian group \(O_K\) is \(n\), then it is easy to see that \(O_K/(m)\) is isomorphic to \(\mathbb{Z}_m^n\), hence \(|O_K/(m)| = m^n\). Also, \((m) \subset I\) implies that the mapping

\[
\phi : O_K/(m) \rightarrow O_K/I, x + (m) \mapsto x + I
\]

is a well-defined surjective homomorphism. Therefore \(O_K/I\) is finite. \[\square\]
Corollary 11.5 If $I$ is a nonzero ideal in a number ring $O_K$, then the rank of $I$ as a free abelian group is the same as that of $O_K$.

Proof If $\rk O_K = n$ and $\rk I = r$, then $r \leq n$ (Theorem E.3). There is a basis $(e_1, \ldots, e_n)$ of $O_K$ and elements $d_1, \ldots, d_r \in \mathbb{Z}$, with $d_i \leq d_{i+1}$, such that $(d_1e_1, \ldots, d_re_r)$ is a basis of $I$. We define a mapping $\phi$ from $O_K$ onto $\mathbb{Z}_{d_1} \times \cdots \times \mathbb{Z}_{d_r} \times \mathbb{Z}^{n-r}$ by

$$\phi(x_1e_1 + \cdots + x_ne_n) = (x_1 + d_1Z, \ldots, x_r + d_rZ, x_{r+1}, \ldots, x_n).$$

It is clear that $\phi$ is a surjective group homomorphism. Also,

$$\ker \phi = \{x_1e_1 + \cdots + x_ne_n : x_1 \in d_1Z, \ldots, x_r \in d_rZ, x_{r+1} = \cdots = x_n = 0\} = I.$$

Hence, as groups,

$$O_K/I \simeq \mathbb{Z}_{d_1} \times \cdots \times \mathbb{Z}_{d_r} \times \mathbb{Z}^{n-r}.$$

However, $O_K/I$ is finite, so the last term on the right-hand side must be $\{0\}$, i.e., $r = n$. □

The next property of ideals in number rings is useful.

Proposition 11.13 If $I$ is a nonzero ideal in a number ring $O_K$, then there is a nonzero integer $\alpha$ in $I$.

Proof Let $\alpha$ be a nonzero element of $I$. There exists a monic polynomial $f \in \mathbb{Z}[X]$ such that $f(\alpha) = 0$. We may suppose that the constant term of $f$ is nonzero. (If not, we may write $f(X) = X^rg(X)$, with $g(0) \neq 0$ and $g(\alpha) = 0$ and replace $f$ by $g$.) Then,

$$\alpha|f(\alpha) - f(0) \implies f(\alpha) - f(0) \in I.$$

Now, $f(\alpha) - f(0) = -f(0) \in \mathbb{Z}^*$, therefore $I$ has a nonzero integer $\alpha$. □

Remark As $Z \subset O_K$, the set $Z\alpha \subset I$, so there is an infinite number of nonzero integers in $I$.

We now consider prime ideals in a number ring.

Theorem 11.16 If $I$ is a nonzero prime ideal in a number ring $O_K$, then $I$ is a maximal ideal.

Proof From Proposition 11.12 we know that $O_K/I$ is a finite ring. If $I$ is a prime ideal, then the quotient ring $O_K/I$ is an integral domain. However, a finite integral domain is a field. This implies that $I$ is a maximal ideal. □

We recall that a ring $R$ is noetherian if every ascending sequence of ideals $I_0 \subset I_1 \subset \cdots$ is finally stationary, i.e., there exists an ideal $I_k$ in the sequence such that $I_k = I_{k+1} = \cdots$. This condition is equivalent to showing that every ideal $I$ in $R$ is finitely generated.

Theorem 11.17 A number ring $O_K$ is noetherian.

Proof We will show that every ideal $I$ in $O_K$ is finitely generated. If $I = \{0\}$, then there is nothing to prove, so let us suppose that $I$ is nonzero. $I$ is a free abelian group of rank $n$, the rank of $O_K$. Thus $I$ has a finite basis and so is finitely generated. □

An integral domain $D$ is said to be a Dedekind domain if it has the following properties:

132
• $D$ is normal;
• $D$ is noetherian;
• every nonzero prime ideal in $D$ is maximal.

We have shown above that a number ring is a Dedekind domain. As many of the properties of number rings are derived from their properties as Dedekind domains, for the moment we will handle the more general case. Later we will return to the more specific case of number rings.
Chapter 12

Dedekind domains

In the last chapter we defined the notion of a Dedekind domain and we saw that number rings are examples of such domains. Dedekind domains are not in general UFDs. However, we will see that the ideals have an interesting factorization similar to that found in UFDs. This statement will be made more precise in the following. We will begin with some preliminary results.

Exercise 12.1 Show that \( \mathbb{Z}[\sqrt{-5}] \) is a Dedekind domain. Prove that 2 is irreducible in \( \mathbb{Z}[\sqrt{-5}] \), but not prime, and so deduce that \( \mathbb{Z}[\sqrt{-5}] \) is not a UFD.

12.1 Elementary results

We have seen in the last chapter that number rings are Dedekind domains. There is another large class of Dedekind domains.

**Theorem 12.1** A principal ideal domain is a Dedekind domain.

**Proof** Let \( R \) be a PID. As every ideal in \( R \) is generated by a unique element, \( R \) is noetherian.

Next we show that \( R \) is a normal domain. Let \( x = \frac{a}{b} \) be an element of the field of fractions of \( R \). We suppose that \( a \) and \( b \) are coprime. If \( x \) is algebraic over \( R \), then there exists an equation of the form

\[
a_0 + a_1 \left( \frac{a}{b} \right) + \cdots + a_{n-1} \left( \frac{a}{b} \right)^{n-1} + \left( \frac{a}{b} \right)^n = 0,
\]

where the \( a_i \) belong to \( R \). Multiplying by \( b^n \) we obtain an equation

\[
bc + a^n = 0
\]

with \( c \in R \). Hence \( bc = -a^n \). As \( R \) is a UFD and \( a \) and \( b \) are coprime, \( b \) is a unit and it follows that \( b^{-1} \in R \). Hence \( x = \frac{a}{b} \in R \). Therefore \( R \) is a normal domain.

It remains to show that a nonzero prime ideal is maximal. Let \( (a) \) be a prime ideal in \( R \). \( (a) \) is included in a maximal ideal \( (b) \) and there exists \( k \in R \) such that \( a = kb \). As \( a \) is prime, \( a \) is irreducible, which implies that \( k \) is invertible and it follows that \((a) = (b)\). \( \square \)

To continue, we need two lemmas, the second depending on the first.

**Lemma 12.1** In a Dedekind domain \( D \) every nonzero ideal \( I \) contains a product of nonzero prime ideals.

134
PROOF Suppose that the proposition is not true and let $C$ be the collection of nonzero ideals in $D$ which do not contain a product of nonzero prime ideals. As $D$ is noetherian, $C$ contains a maximal element $M$. (If not, then it would be possible to create an infinite chain of distinct ideals, contradicting the noetherian hypothesis.) As $M \in C$, $M$ is not a prime ideal, hence there exist $x, y \in D \setminus M$ such that $xy \in M$. Clearly, $M$ is strictly contained in the ideals $M + (x)$ and $M + (y)$, which are not elements of $C$, because $M$ is maximal. It follows that $M + (x)$ and $M + (y)$ both contain products of nonzero prime ideals, so the ideal $(M + (x))(M + (y))$ also contains a product of nonzero prime ideals. As this ideal is included in $M$, which is an element of $C$, we have a contradiction. \hfill $\square$

The proof of the second lemma is a little longer.

**Lemma 12.2** Let $D$ be a Dedekind domain, with fraction field $K$, and $I$ a proper ideal in $D$. Then there exists $\alpha \in K \setminus D$ such that $\alpha I \subset D$.

PROOF If $I = \{0\}$, then the result is obvious, so let us suppose that this is not the case. We fix $a \neq 0$ in $I$. From Lemma 12.1, the principal ideal $(a)$ contains a product of nonzero prime ideals. We take such a product $P_1 \ldots P_r$, with $r$ minimal. If $r = 1$, then we have

$$P_1 \subset (a) \subset I = P_1,$$

because $P_1$ is maximal, hence $I = (a)$. Since $I$ is a proper ideal in $D$, we can take $b \in D \setminus (a)$; then $\alpha = \frac{b}{a} \notin D$, because in this case we would have $b \in (a)$, a contradiction. If $x \in I$ then there exists $s \in D$, such that $x = sa$, hence

$$\alpha x = \frac{b}{a}x = \frac{b}{a}sa = b \in D,$$

so for $r = 1$ the statement is true.

Now suppose that $r > 1$. Since $I$ is a proper ideal in $D$, Zorn’s lemma ensures that there exists a maximal ideal $M$ such that $I \subset M$. The ideal $M$ contains at least one of the ideals $P_i$. (If not, then, for all $i$, there exists $a_i \in P_i \setminus M$; however, the product $a_1 \ldots a_r \in M$, which is prime, implying that a certain $a_j \in M$, a contradiction.) If $P_j$ is a prime ideal contained in $M$, then $P_j = M$, because all nonzero prime ideals are maximal. Without loss of generality let us suppose that $j = 1$. As $r$ is minimal, there exists $b \in (P_2 \ldots P_r) \setminus (a)$. We consider $\alpha = \frac{b}{a}$. As above $\alpha \notin D$, hence $\alpha \in K \setminus D$. Then

$$IP_2 \cdots P_r \subset MP_2 \cdots P_r = P_1P_2 \cdots P_r \subset (a) \Rightarrow Ib \subset (a).$$

Hence, if $x \in I$ then there exists $s \in D$, such that $xb = sa$, which implies that

$$\alpha x = \frac{b}{a}x = s \in D$$

and so $\alpha I \subset D$. \hfill $\square$

We may now establish a result which will prove important further on, but is also interesting in its own right.

**Theorem 12.2** If $I$ is an ideal in a Dedekind domain, then there is a nonzero ideal $J$ in $D$ such that $IJ$ is a principal ideal.
PROOF If \( I = \{0\} \), then we may take any ideal in \( D \) for \( J \), because in this case \( IJ = \{0\} \), which is a principal ideal. So let us now take \( I \) nonzero. We choose \( a \in I \), with \( a \neq 0 \) and set \( J = \{b \in D : a\mid b \} \). Then \( J \) is a nonzero ideal and \( IJ \subset (a) \).

Let us now consider the set \( A = \frac{1}{a}IJ \). As \( IJ \subset (a) \), \( A \subset D \); also \( A \) is an ideal in \( D \). If \( A = D \), then \( IJ = (a) \) and we have the result we are looking for. If this is not the case, then \( A \) is a proper ideal in \( D \) and we can apply Lemma 12.2: there exists \( \gamma \in K \setminus D \) such that \( \gamma A \subset D \).

We now notice that \( A \) contains \( J \): as \( a \in I \), \( 1 = \frac{1}{a}a \in \frac{1}{a}I \), hence \( J \subset \frac{1}{a}IJ \). It follows that \( \gamma J \subset \gamma A \subset D \). This allows us to show that \( \gamma J \subset J \):

\[
\gamma A \subset D \implies \gamma IJ \subset (a) \implies (\gamma J)I \subset (a) \implies \gamma J \subset J.
\]

As \( D \) is noetherian, the ideal \( J \) has a finite generating set \( a_1, \ldots, a_m \). Using the relation \( \gamma J \subset J \), we may find a matrice \( M \in M_m(D) \) such that

\[
\gamma \begin{pmatrix} a_1 \\ \vdots \\ a_m \end{pmatrix} = M \begin{pmatrix} a_1 \\ \vdots \\ a_m \end{pmatrix},
\]

which implies that

\[
(\gamma I_m - M) \begin{pmatrix} a_1 \\ \vdots \\ a_m \end{pmatrix} = \begin{pmatrix} 0 \\ \vdots \\ 0 \end{pmatrix}.
\]

As the \( a_i \) are not all 0, we have \( \det(\gamma I_m - M) = 0 \). Thus \( \gamma \) is the root of a polynomial \( f \in D[X] \). However, \( D \) is a normal domain, so \( \gamma \in D \), a contradiction. We have shown that \( IJ = (a) \), i.e., \( IJ \) is principal. \( \square \)

The result which we have just proved has two immediate consequences. The first of these is a cancellation rule for ideals in a Dedekind domain.

**Corollary 12.1** If \( A, B \) and \( C \) are ideals in a Dedekind domain \( D \), with \( A \) nonzero, then

\[
AB = AC \implies B = C.
\]

**Proof** There exists a nonzero ideal \( J \) such that \( AJ \) is principal: \( AJ = (a) \), with \( a \neq 0 \), because \( A \) and \( J \) are nonzero. Hence,

\[
AB = AC \implies AJB = AJC \implies (a)B = (a)C \implies aB = aC.
\]

Multiplying by \( a^{-1} \), we obtain \( B = C \). \( \square \)

In a commutative ring \( R \) we may define a division on ideals in a natural way. If \( I \) and \( J \) are ideals, then we say that \( I \) divides \( J \), and write \( I|J \), if there exists an ideal \( K \) such that \( IK = J \). In Dedekind domains this is equivalent to an inclusion condition.

**Corollary 12.2** If \( A \) and \( B \) are ideals in a Dedekind domain, then

\[
A|B \iff A \supset B.
\]

**Proof** If \( A \) divides \( B \), then there exists an ideal \( C \) such that \( AC = B \). If \( b \in B \), then there exist \( a_1, \ldots, a_s \in A \) and \( c_1, \ldots, c_s \in C \) such that \( b = a_1c_1 + \cdots + a sc_s \). However, \( a_i c_i \in A \), for all \( i \), and so \( b \in A \). Therefore \( B \subset A \).
Now suppose that $A \supset B$. If $A = \{0\}$, then $B = \{0\}$ and it is clear that $A$ divides $B$. Suppose now that $A \neq \{0\}$. There exists a nonzero ideal $J$ and $a \in D^*$ such that $AJ = (a)$. Let us set $C = \frac{1}{a}JB$. Then

$$B \subset A \implies \frac{1}{a}JB \subset \frac{1}{a}JA = \frac{1}{a}(a) = D.$$ 

It is easy to see that $C$ is an ideal in $D$. We have

$$AC = A\frac{1}{a}JB = DB = B$$

and so $A$ divides $B$.

\[ \square \]

### 12.2 Prime factorization of ideals

We have seen that a nonzero ideal in a Dedekind domain contains a product of nonzero prime ideals. In fact, we can strengthen this statement.

**Theorem 12.3** In a Dedekind domain $D$, every ideal $I \neq \{0\}, D$ can be expressed in a unique way as a product of nonzero prime ideals.

**Proof** Suppose that there exists an ideal $I \neq \{0\}, D$ which cannot be expressed as a product of prime ideals. As $D$ is noetherian, the collection of such ideals has a maximal element $M$. The ideal proper $M$ is included in a maximal ideal $P$. As $P$ is a maximal ideal, $P$ is a prime ideal. However, from Corollary 12.2, $P \supset M$ implies that $P|M$, i.e., there exists an ideal $I$ such that $PI = M$. Using Corollary 12.2 again, we obtain $I \supset M$. If $I = M$, then, using Corollary 12.1, 

$$DM = DPI = PDM = PM \implies D = P,$$

a contradiction. Hence we have $M \subsetneq I$ and so $I$ is a product of prime ideals. As $M = PI$, $M$ is also a product of prime ideals, which is a contradiction. It follows that any ideal $I \neq \{0\}, D$ is a product of prime ideals.

We now consider the uniqueness. Suppose that

$$P_1P_2 \cdots P_r = Q_1Q_2 \cdots Q_s,$$

where the $P_i$ and $Q_j$ are nonzero prime ideals (not necessarily distinct). Then

$$P_1|Q_1Q_2 \cdots Q_s \implies P_1 \supset Q_1,$$

for some $i$ (see the proof of Lemma 12.2). Without loss of generality, let us suppose that $i = 1$. As $Q_1$ is maximal, $P_1 = Q_1$. Using Corollary 12.1 we obtain

$$P_2 \cdots P_s = Q_2 \cdots Q_r.$$

Continuing in the same way we obtain the postulated uniqueness. \[ \square \]

**Corollary 12.3** In a Dedekind domain a countable intersection of distinct nonzero prime ideals is trivial.
Let \((P_n)_{n \in \mathbb{N}}\) be a collection of distinct nonzero prime ideals in a Dedekind domain \(D\) and \(I = \cap_{n \in \mathbb{N}} P_n\). We have
\[ P_n \supset I \implies P_n | I, \]
for each \(n\). If \(I\) is nontrivial, then \(I\) has a unique decomposition into prime ideals and each \(P_n\) must appear in this decomposition. This is impossible, because the decomposition is composed of a finite number of prime ideals. Hence the result.

An integral domain which is principal ideal domain (PID) is always a unique factorization domain (UFD). For a Dedekind domain the converse is also true. This is a corollary of the theorem which we have just proved.

**Corollary 12.4** A Dedekind domain which is a UFD is a PID.

**Proof** Let \(D\) be a Dedekind domain and \(I\) an ideal in \(D\). If \(I = \{0\}\) or \(I = D\), then \(I\) is clearly principal, so let us suppose that this is not the case. From Theorem 12.2, \(I\) divides a nonzero principal ideal \((a)\). As \(D\) is a UFD, we may write \(a\) as a product of irreducible elements: \(a = p_1 \cdots p_s\). Each principal ideal \((p_i)\) is a prime ideal and we have
\[ (a) = (p_1) \cdots (p_s). \]
As \(I\) divides \((a)\), there exists an ideal \(C\) such that
\[ IC = (p_1) \cdots (p_s). \]
By Theorem 12.3 there exist \((p_{i_1}), \ldots, (p_{i_u})\) such that
\[ I = (p_{i_1}) \cdots (p_{i_u}) = (p_{i_1} \cdots p_{i_u}). \]
We have shown that \(I\) is a principal ideal.

**Remark** We might be tempted to think that the ideals in a Dedekind domain form a UFD. However, the ideals in a nontrivial ring do not form an additive group: If \(I\) is a nonzero ideal, then \(I + I = I\), which would not be possible if \(I\) had an additive inverse. We can only affirm that the ideals form a monoid.

### 12.3 Ideal classes

If \(R\) is an integral domain, then we may define a relation \(\mathcal{R}\) on the nonzero ideals in \(R\) as follows: \(I \mathcal{R} J\) if and only if there exist elements \(\alpha, \beta \in R \setminus \{0\}\) such that \(\alpha I = \beta J\). It is easy to see that \(\mathcal{R}\) is an equivalence relation, so we will write \(\sim\) for \(\mathcal{R}\). We define a multiplication on the equivalence classes in an obvious way:
\[ [I][J] = [IJ]. \]
This multiplication is well-defined, since \(I \sim I’\) and \(J \sim J’\) implies that \(IJ \sim I’J’\). We will show that the equivalence classes with this multiplication form a monoid and, in the case of a Dedekind domain, a group.

**Lemma 12.3** If \(R\) is an integral domain, \(I\) an ideal in \(R\) and there exists \(\alpha \neq 0\) such that \(\alpha I\) is principal, then \(I\) is principal.
Let \( \alpha I = (a) \). Then there exists \( u \in I \) such that \( a = \alpha u \). We have
\[
\alpha s = vu \Rightarrow \alpha (s - vu) = 0 \Rightarrow s = vu.
\]

It follows that \( I \subset (u) \). As \( u \in I \), \( (u) \subset I \) and so we have \( I = (u) \). \( \square \)

We now consider a particular equivalence class.

**Proposition 12.1** If \( R \) is an integral domain, then the nonzero principal ideals form an equivalence class.

**proof** Let \( I \) be a nonzero principal ideal: \( I = (a) \). If \( J \) is also a nonzero principal ideal and \( J = (b) \), then
\[
b(a) = a(b) \Rightarrow I \sim J,
\]
hence \( J \in [I] \).

Now suppose that \( J \) is a nonzero ideal in \( R \) and \( I \sim J \): there exist \( \alpha, \beta \in R \setminus \{0\} \) such that \( \alpha I = \beta J \). If \( I = (a) \), then \( \beta J = \alpha(a) = (aa) \). From Lemma 12.3, \( J \) is principal. Therefore the class of \( I \) is composed of the nonzero principal ideals in \( R \). \( \square \)

We will note the set of equivalence classes \( Cl(R) \). Clearly, \( Cl(R) \) contains a unique element if and only if \( R \) is a PID.

**Theorem 12.4** \( Cl(R) \) is a monoid. If \( R \) is a Dedekind domain, then \( Cl(R) \) is a group.

**proof** It is clear that the multiplication which we have defined is associative. We claim that the class of nonzero principal ideals, which we note \( E \), is a neutral element. To see this, let \( (a) \) be a nonzero principal ideal and \( I \) any nonzero ideal. Then \( (a)I = aI \). As \( aI = 1aI \), \( I \sim aI \) and it follows that \( E[I] = [I] \). Thus \( Cl(R) \) is a monoid.

Now suppose that \( R \) is a Dedekind domain and \( I \) a nonzero ideal. From Theorem 12.2 we know that there is a nonzero ideal \( J \) such that \( IJ \) is principal. Moreover, \( IJ \neq \{0\} \), since \( I \neq \{0\} \) and \( J \neq \{0\} \). Hence the class \([I]\) has an inverse \([J]\). Therefore \( Cl(R) \) is a group. \( \square \)

The group of classes \( Cl(D) \) of a Dedekind domain \( D \) is called the **ideal class group** of \( D \).

### 12.4 hcf and lcm

We have seen above that division of ideals in a Dedekind domain may be characterized by a simple inclusion condition: \( IJ \iff I \supset J \). Keeping this in mind, we will now study in more detail the division of ideals in a Dedekind domain.

We define a **highest common factor** (hcf) and a **lowest common multiple** (lcm) of two ideals in the same way as we do in an integral domain. Let \( I \) and \( J \) be nontrivial, proper ideals in a Dedekind domain \( D \). An ideal \( U \) is an hcf of \( I \) and \( J \) if

- \( U \mid I, U \mid J \);
- \( X \mid I, X \mid J \Rightarrow X \mid U \).

An ideal \( V \) is an lcm of \( I \) and \( J \) if
Exercise 12.2 Show that the hcf and the lcm are unique; hence we can speak of the hcf and the lcm of two ideals.

Another point is worth making. We say that two elements in an integral domain are coprime if they have 1 as an hcf. If $R$ is a PID and $x$ and $y$ are coprime, then there exist $a, b \in R$ such that $ax + by = 1$. This is equivalent to saying that $(x) + (y) = R$. This suggests the following generalization: if $I$ and $J$ are ideals in ring $R$, then we say that these ideals are coprime, if $I + J = R$.

Proposition 12.2 If $I$ and $J$ are nontrivial, proper ideals in a Dedekind domain $D$, then

$$\text{hcf}(I, J) = I + J \quad \text{and} \quad \text{lcm}(I, J) = I \cap J.$$  

Proof First the hcf. We have

$$I + J \supset I, J \implies I + J | I, I + J | J,$$

and

$$X|I, X|J \implies X \supset I, X \supset J \implies X + I \supset J \implies X | I + J,$$

hence $\text{hcf}(I, J) = I + J$.

Now we consider the lcm. We have

$$I, J \supset I \cap J \implies I|I \cap J, J|I \cap J$$

and

$$I|Y, J|Y \implies I \supset Y, J \supset Y \implies I \cap J \supset Y \implies I \cap J|Y,$$

hence $\text{lcm}(I, J) = I \cap J$. $\square$

The following characterizations of the hcf and lcm are not difficult to establish:

Proposition 12.3 Let $D$ be a Dedekind domain and $I, J$ nontrivial, proper ideals in $D$. We note $P_1, \ldots, P_s$ the prime ideals appearing in the factorization into products of prime ideals in either $I$ or $J$:

$$I = \prod_{i=1}^{s} P_i^{m_i} \quad \text{and} \quad J = \prod_{i=1}^{s} P_i^{n_i},$$

where the $m_i$ and the $n_i$ are elements of $\mathbb{N}$ and, for any given $i$, $m_i$ and $n_i$ are not both equal to 0. Then

$$\text{hcf}(I, J) = \prod_{i=1}^{s} P_i^{\min(m_i, n_i)} \quad \text{and} \quad \text{lcm}(I, J) = \prod_{i=1}^{s} P_i^{\max(m_i, n_i)}.$$  

Corollary 12.5 If $I, J$ are nontrivial, proper ideals in a Dedekind domain $D$, then

$$\text{hcf}(I, J)\text{lcm}(I, J) = IJ.$$  

Remark Propositions 12.2 and 12.3 can be naturally generalized to a finite number of ideals.

The following result is also useful:
Proposition 12.4 In a commutative ring $R$, if the ideals $I$ and $J$ are coprime, then $I \cap J = IJ$.

If $R$ is a Dedekind domain and $I$, $J$ are nontrivial, proper ideals, then the converse is also true.

Proof Let $R$ be a commutative ring with ideals $I$ and $J$. If $I + J = R$, then

$$I \cap J = (I \cap J)R = (I \cap J)(I + J) = (I \cap J)I + (I \cap J)J \subset IJ + IJ = IJ.$$

Clearly $IJ \subset I \cap J$, so $I \cap J = IJ$.

Now suppose that $R$ is a Dedekind domain. Then

$$IJ = I \cap J \implies (I + J)(IJ) = (I + J)(I \cap J) = IJ,$$

because $I + J = \text{hcf}(I, J)$ and $I \cap J = \text{lcm}(I, J)$. If $I + J$ is a nontrivial, proper ideal, then we have a contradiction to the unique factorization of ideals. On the other hand, clearly $I + J \neq \{0\}$, so $I + J = D$, i.e., $I$ and $J$ are coprime. \qed

We may slightly strengthen Theorem 12.2. To do so we need a preliminary result.

Lemma 12.4 Let $I$ be a nonzero ideal in a Dedekind domain $D$. If $P$ is a prime ideal, then $PI \subset I$ and the inclusion is strict.

Proof The inclusion is clear. If $I = D$, then the strict inclusion is clear. On the other hand, if $I \neq D$, if the inclusion is not strict, then we have a contradiction to the unicity of the factorization of ideals, so the inclusion must be strict. \qed

Theorem 12.5 If $I$ and $Q$ are nonzero ideals in a Dedekind domain $D$, then there exists an ideal $J$ of $D$ such that $IJ$ is principal and $J$ and $Q$ are coprime.

Proof If $I = D$, then it is sufficient to take $J = \{0\}$. On the other hand, if $Q = D$, then, from Theorem 12.2, there is a nonzero ideal $J$ such that $IJ$ is principal; as $J + D = D$, $J$ and $D$ are coprime. Let us now suppose that $I \neq D$ and $Q \neq D$.

Let $P_1, \ldots, P_s$ be the prime ideals which occur in the decomposition into prime ideals of $I$ and $Q$. Then

$$I = P_1^{m_1} \cdots P_s^{m_s},$$

with $m_i \geq 0$, for $i = 1, \ldots, s$. If $m_i = 0$, then $P_i^{m_i} = D$. From Lemma 12.4, for each $i \in \{1, \ldots, s\}$, we can find $y_i \in P_i^{m_i} \setminus P_i^{m_i+1}$. Also, if $i \neq j$, then from Proposition 12.3

$$\text{hcf}(P_i^{j+1}, P_j^{j+1}) = P_i^0 P_j^0 = D,$$

so $P_i^{j+1}$ and $P_j^{j+1}$ are coprime. From the Chinese remainder theorem (Theorem F.1), we see that there exists $x \in D$ such that $x \equiv y_i \mod P_i^{m_i+1}$, for each $i \in \{1, \ldots, s\}$. Thus, for all $i \in \{1, \ldots, s\}$,

$$x \in P_i^{m_i}, \ x \notin P_i^{m_i+1} \implies P_i^{m_i} | (x), \ P_i^{m_i+1} \nmid (x).$$

This implies that $IJ | (x)$ and so there exists an ideal $J$ in $D$ such that $IJ = (x)$. $J$ and $Q$ are coprime, since no prime ideal divides both $J$ and $Q$. Indeed, any prime ideal dividing both $J$ and $Q$ is a $P_i$ for some $i \in \{1, \ldots, s\}$. This contradicts the fact that $x \notin P_i^{m_i+1}$. \qed

Dedekind domains are 'almost principal', i.e., their ideals are generated by at most two elements.
Corollary 12.6 If $I$ is an ideal in a Dedekind domain $D$, then there exist $x, y \in I$ such that $I = (x, y)$.

**Proof** From Theorem 12.2 we know that there is a nonzero ideal $Q$ in $D$ such that $IQ$ is principal: there exists $y \in D$ such that $IQ = (y)$. In addition, Theorem 12.5 ensures the existence of an ideal $J$ in $D$ such that $IJ$ is principal and $J$ and $Q$ coprime: $IJ = (x)$, for some $x \in IJ$. We have

$$(x, y) = (x) + (y) = IJ + IQ = I(J + Q) = ID = I,$$

the result we were looking for. \(\square\)

We have seen above in Corollary 12.4 that a Dedekind domain which is a UFD is a PID. We can use Theorem 12.5 to obtain another criterion for a Dedekind domain to be a PID.

**Corollary 12.7** A Dedekind domain with only a finite number of prime ideals is a PID.

**Proof** Let $D$ be a Dedekind domain with only a finite number of prime ideals. We write $Q$ for the product of these ideals. If $I$ is a nonzero ideal in $D$, then from Theorem 12.5 there is an ideal $J$ such that $IJ$ is a principal ideal $(a)$, with $J$ and $Q$ coprime. As $J$ and $Q$ are coprime, we must have $J = D$. Hence

$$(a) = IJ = ID = I,$$

therefore $I$ is principal. \(\square\)

### 12.5 Fractional ideals

If $R$ is a commutative ring, then by definition $R$ is an $R$-module and an ideal of $R$ is an $R$-submodule. In an integral domain we may extend the notion of ideal. This proves to be particularly useful in Dedekind domains. Let $R$ be an integral domain with field of fractions $K$. If $J$ is an $R$-submodule of $K$ such that $rJ \subset R$, for some $r \in R^*$, then we say that $J$ is a fractional ideal. We call $r$ a denominator of $J$. Setting $r = 1$, we see that an ordinary ideal is a fractional ideal, so the notion of fractional ideal does indeed generalize that of ideal. When handling fractional ideals we sometimes refer to ordinary ideals as *integral ideals* to distinguish them.

**Example** $\frac{1}{2} \mathbb{Z}$ is a fractional ideal of $\mathbb{Z}$, but not an integral ideal.

The ring $R$ is a fractional ideal, but in general its field of fractions $K$ is not. If $K$ is a fractional ideal, then there exists $r \in R^*$ such that $rK \subset R$. As $r$ is invertible in $K$, we have $K = \frac{1}{r}R$. Now, $\frac{1}{2} \in K$, so $\frac{1}{2} = \frac{1}{2}s$, with $s \in R$. This implies that $s = \frac{1}{2}$, i.e., $\frac{1}{2} \in R$, and so $K = R$. We will suppose that $K \neq R$.

We define the addition and multiplication of fractional ideals in the same way as we do for ideals, i.e.,

$$I + J = \{x + y : x \in I, y \in J\} \quad \text{and} \quad I \cdot J = \left\{\sum_{i=1}^{n} x_i y_i : n \geq 1, x_i \in I, y_i \in J\right\}.$$

As in general for multiplication, we write $IJ$ for $I \cdot J$.

**Proposition 12.5** If $I$ and $J$ are fractional ideals with denominators $r$ and $s$ respectively, then $I \cap J$, $I + J$ and $IJ$ are fractional ideals with respective denominators $r$, $s$, $rs$ and $rs$. 

142
There is no difficulty in seeing that $I \cap J$, $I + J$ and $IJ$ are $R$-submodules of $K$. In addition,

$$r(I \cap J) \subset rI \subset R, \quad rs(I + J) \subset rI + sJ \subset R \quad \text{and} \quad rs(IJ) = (rI)(sJ) \subset R.$$  

This ends the proof.

**Proposition 12.6** Let $R$ be an integral domain. The nonzero fractional ideals of $R$ are the expressions of the form $J = \alpha I$, where $I$ is a nonzero ideal of $R$ and $\alpha \in K^\ast$.

**Proof** Let $J = \alpha I$, where $I$ is a nonzero ideal of $R$ and $\alpha \in K^\ast$. If $\alpha = \frac{a}{b}$, with $a, b \in R^\ast$, then $bJ = aI \subset I \subset R$, therefore $J$ is a nonzero fractional ideal of $R$.

Now let $J$ be a nonzero fractional ideal of $R$. There exists $r \in R^\ast$ such that $rJ \subset R$. Moreover, $J = \frac{1}{r}(rJ)$ and $rJ$ is an ideal of $R$. As $\frac{1}{r} \in K^\ast$, $J$ has the required form.

**Remark** An $R$-submodule is not necessarily a fractional ideal. For example, $\mathbb{Z}[\frac{1}{2}]$ is a $\mathbb{Z}$-submodule contained in $\mathbb{Q}$, but is not a fractional ideal of $\mathbb{Z}$. (There is no positive integer $n$ such that $n\mathbb{Z}[\frac{1}{2}] \subset \mathbb{Z}$).

**Exercise 12.3** Let $R$ be an integral domain. Prove the following statements:

- **a.** If $J$ is a fractional ideal of $R$ and $r$ a denominator, then $rJ$ is an integral ideal of $R$.
- **b.** If a fractional ideal $J$ of a ring $R$ is contained in $R$, then $J$ is an integral ideal of $R$.

The next result enables us to characterize fractional ideals in the case where the ring $R$ is noetherian.

**Proposition 12.7** Let $R$ be a noetherian domain. The nonzero fractional ideals of $R$ are the nonzero finitely generated $R$-submodules of $K$, where $K$ is the field of fractions of $R$.

**Proof** Let $J$ be a nonzero finitely generated $R$-submodule of $K$:

$$J = Rx_1 + \cdots + Rx_n,$$

where $x_i = \frac{a_i}{b_i}$, with $a_i \in R$ and $b_i \in R^\ast$. If we set $b = b_1 \cdots b_n$, then $bJ \subset R$ and so $J$ is a nonzero fractional ideal of $R$.

Reciprocally, let $J$ be a nonzero fractional ideal of $R$ and $r$ a denominator of $J$. Then $J \subset \frac{1}{r}R$. As an $R$-module, $\frac{1}{r}R$ is isomorphic to $R$, hence $\frac{1}{r}R$ is a noetherian $R$-module. Since $J$ is a submodule of $\frac{1}{r}R$, $J$ is a finitely generated $R$-module.

The product of two nonzero fractional ideals is a nonzero fractional ideal and the multiplication is associative. If $J$ is a fractional ideal, then, using the fact that $J$ is an $R$-module, we have

$$RJ \subset J \subset RJ,$$

and so $R$ is an identity for the multiplication. It follows that the nonzero fractional ideals form a semigroup. In the case of a Dedekind domain the nonzero fractional ideals form a group, as we will presently see.

**Proposition 12.8** Every nonzero fractional ideal in a Dedekind domain $D$ has an inverse in the set of fractional ideals. More explicitly, if $I$ is a nonzero fractional ideal of $D$ and $J = \{x \in K, xI \subset D\}$, then $J$ is a fractional ideal and $IJ = D$.  

143
**Proposition 12.9** Let us first suppose that $I$ is a nonzero integral ideal. It is easy to see that $J$ is a nonzero $D$-submodule of $K$, the field of fractions of $D$. If $r$ is a nonzero element of $I$ (and so of $R$) and $x \in J$, then $rx \in D$, so there exists $r \in D^*$ such that $rJ \subset D$. Thus $J$ is a nonzero fractional ideal.

Let $a \in I$, with $a \neq 0$, and $J_a = \{b \in D : bl \subset (a)\}$. The proof of Theorem 12.2 shows that $IJ_a = (a)$. Indeed, $J_a J_a$ is clearly included in $J$ and every $c \in J$ can be written $c = \frac{1}{a}ca$ and $ca \in J_a$. Thus

$$IJ = I - J_a = \frac{1}{a}(a) = D,$$

therefore $J$ is an inverse of $I$.

Now let us consider the more general case, i.e., $I$ is a nonzero fractional ideal, which is not necessarily integral. There exists a nonzero integral ideal $A$ and $a \in K^*$, where $K$ is the field of fractions of $D$, such that $I = aA$ (Proposition 12.6). If we set $B = a^{-1}A^{-1}$, then $B$ is a fractional ideal and $IB = D$, so $I$ has an inverse, namely $B$. It remains to show that $B = J = \{x \in K : xI \subset D\}$. From the first part of the proof we know that $A^{-1} = \{x \in K : xA \subset D\}$. If $u \in I^{-1}$, then $u = \alpha^{-1}x$, where $xA \subset D$, which implies that $uaA \subset D$ and it follows that $u \in J$. We have shown that $I^{-1} \subset J$. To complete the proof, we show that $J \subset I^{-1}$. If $u \in J$, then $uI \subset D$, i.e., $uaA \subset D$. This implies that $ua \in A^{-1}$ and so $u \in \alpha^{-1}A^{-1} = I^{-1}$. Therefore $J \subset I^{-1}$.

**Corollary 12.8** The nonzero fractional ideals of a Dedekind domain form an abelian group.

In fact, Proposition 12.8 has a converse. If $R$ is an integral domain, then the nonzero fractional ideals form a monoid, with identity $R$. The nonzero invertible fractional ideals form an abelian group. If $R$ is a Dedekind domain, then every nonzero fractional ideal is invertible, hence the result of Corollary 12.8. However, the converse is also true.

**Proposition 12.9** If $R$ is an integral domain such that every nonzero fractional ideal is invertible, then $R$ is a Dedekind domain.

**Proof** We must show that $R$ is noetherian, that prime ideals are maximal and that $R$ is normal. Let $K$ be the field of fractions of $R$.

Let $I$ be a nonzero (integral) ideal of $R$. Then $I$ is invertible and $J = \{x \in K : xI \subset R\}$ is the inverse of $I$. (We can easily verify that $IJ = R$ and in a monoid, if an element has an inverse, then this inverse is unique.)

As $IJ = R$, there exist $a_1, \ldots, a_n \in I$ and $b_1, \ldots, b_n \in J$ such that $a_1b_1 + \cdots + a_nb_n = 1$. If $a \in I$, then

$$a = a_1(b_1a) + \cdots + a_nb_n(a_1, \ldots, a_n),$$

because $b_ia \in R$, for $i = 1, \ldots, n$. It follows that $I \subset (a_1, \ldots, a_n)$. Clearly $(a_1, \ldots, a_n) \subset I$, so we have equality. As every ideal is finitely generated, $R$ is noetherian.

Let $P$ be a prime ideal in $R$ and $M$ a maximal ideal containing $P$. As $M$ is invertible, there exists an ideal $J$ such that $P = JM$. ($J = M^{-1}P \subset R$, because $P \subset M$; from Exercise 12.6 the fractional ideal $J$ is an integral ideal.) Since $P$ is a prime ideal, we have $J \subset P$ or $M \subset P$. (If $J \not\subset P$ and $M \not\subset P$, then there exist $x \in J \setminus P$ and $y \in M \setminus P$; but $xy \in JM = P$, a contradiction.) If $J \subset P$, then $P = JM \subset PM$; multiplying by $P^{-1}$, we obtain $R \subset M$, a contradiction. Therefore $M \subset P$ and it follows that $M = P$. Hence $P$ is a maximal ideal.
It remains to show that $R$ is a normal domain. Let $x \in K$ be integral over $R$. Then there exist elements $c_0, c_1, \ldots, c_{n-1} \in R$ such that $x^n = c_0 + c_1 x + \cdots + c_{n-1} x^{n-1}$. Let

$$A = \{y \in K : y = \sum_{i=0}^{n-1} u_i x^{i}, u_i \in R \}.$$  

$A$ is clearly an $R$-module. The element $x = r s$, with $r \in R$ and $s \in R^\ast$, so $s^{n-1} A$ is a subset of $R$. Hence $A$ is a fractional ideal of $R$. Since $x^n \in A$, we have $x A \subset A$. By hypothesis $A$ is invertible, so multiplying by $A^{-1}$ we obtain $x \in R$. Therefore $R$ is integrally closed in $K$, i.e., $R$ is a normal domain.

**Remark** Propositions 12.8 and 12.9 provide us with a useful characterization of Dedekind domains, which will use further on.

**Decomposition of fractional ideals**

We have seen that in a Dedekind domain $D$ an ideal $I \neq \{0\}, D$ can be written in a unique way as a product of prime ideals. We may extend this result to fractional ideals.

**Theorem 12.6** If $J$ is a fractional ideal in a Dedekind domain and $J \neq \{0\}, D$, then

$$J = P_1^{n_1} \cdots P_r^{n_r},$$

where the $P_i$ are distinct nonzero prime ideals of $D$ and the $n_i$ integers (possibly negative). This decomposition is unique.

**Proof** We first observe that such a decomposition exists. As $J$ is a fractional ideal there is an $r \in D^\ast$ such that $r J \subset D$. Clearly $r J$ is a nonzero ideal of $D$. There are two cases to consider: 1. $r$ is a unit of $D$, 2. $r$ is not a unit of $D$.

**Case 1.** If $r$ is a unit of $R$, then $J$ is subset of $D$, hence an ideal of $D$ (Exercise 12.6). By hypothesis, $J \neq D$, so we have the required decomposition.

**Case 2.** If $r$ is not a unit, then $r D$ is a nonzero proper ideal in $D$ and so there exists a decomposition

$$r D = P_1^{n_1} \cdots P_r^{n_r},$$

where the $P_i$ are distinct prime ideals and the $n_i$ positive integers. From Proposition 12.8 each $P_i$ has an inverse in the set of fractional ideals. Consequently, $r D$ has an inverse in the set of fractional ideals:

$$(r D)^{-1} = P_1^{-n_1} \cdots P_r^{-n_r}. \quad (12.1)$$

As $r J$ is an integral ideal of $D$ (Exercise 12.6), we have $Dr J = r J$, thus

$$r^{-1} Dr J = J \implies (r D)^{-1} r J = J.$$  

If $r J = D$, then $(r D)^{-1} = J$ and, using Equation (12.1), we obtain a decomposition of $J$ of the required type. On the other hand, if $r J \neq D$, then $r J$ is a nonzero proper ideal of $D$ and it follows that $J$ has a decomposition of the required type.
We now consider the unicity of the decomposition. If
\[ P_1^{m_1} \cdots P_r^{m_r} = Q_1^{n_1} \cdots Q_s^{n_s} \]
and all the exponents are positive, then there is no difficulty as we have an ideal in \( D \). The \( P_i \) and \( Q_j \) are the same with the same positive powers. Suppose now that there are negative powers in the expression. If, for example, \( n_s < 0 \), then we may multiply both sides of the expression by \( Q_s^{-n_s} \). If we do this for all prime ideals with negative powers, then we obtain an expression with positive powers of the \( P_i \) and the \( Q_j \) on both sides. If we now have a \( Q_j \) on the lefthand side, then we must have a \( P_i \) on the righthand side such that \( Q_j = P_i \) and \( -n_j = -m_i \), which implies that \( n_j = m_i \). If a \( Q_j \) remains on the lefthand side such that \( Q_j = P_i \) and \( n_j = m_i \). We may use an analogous argument for the \( P_i \) and so obtain the uniqueness of the decomposition.

We may distinguish the integral ideals among the fractional ideals in a simple way, as the next result shows.

**Corollary 12.9** A nonzero fractional ideal \( J \) of a Dedekind domain \( D \), such that \( J \neq D \), is an integral ideal if and only if the powers of all the prime ideals in its decomposition are positive.

**Proof** If all the powers are positive, then we have a product of ideals, which is an ideal.

Suppose now that at least one power \( m_i \) is negative:
\[ J = P_1^{m_1} \cdots P_i^{m_i} \cdots P_r^{m_r}, \]
with \( m_i < 0 \). If \( J \) is an ideal, then we may write
\[ J = Q_1^{n_1} \cdots Q_s^{n_s}, \]
where the \( Q_j \) are ideals and \( n_j > 0 \), for all \( j \). Given the uniqueness of the factorization of \( I \), we must have \( P_i = Q_j \) for some \( j \), and \( m_i = n_j \). However, this is impossible, because
\[ P_i^{m_i} = Q_j^{n_j} \implies P_i^{n_j - m_i} = D \]
and \( n_j - m_i \geq 2 \) and \( P_i \) is a proper ideal. Hence, if a power of a prime ideal in the decomposition is negative, \( J \) is not an ideal. \( \square \)

**Further properties of fractional ideals**

Certain properties of ideals may be generalized to fractional ideals. First we consider divisibility. Let \( I \) and \( J \) be fractional ideals in a Dedekind domain \( D \). We say that \( I \) divides \( J \) if there exists an integral ideal \( H \) such that \( IH = J \).

**Exercise 12.4** Show that division defines an order relation on fractional ideals.

**Exercise 12.5** Show that division of fractional ideals is equivalent to inclusion, i.e., if \( I \) and \( J \) are fractional ideals of a Dedekind domain \( D \), then \( I \) divides \( J \) if and only if \( I \) contains \( J \).

It is also interesting to notice that inclusion is reversed by inversion:

**Exercise 12.6** Let \( I \) and \( J \) be nonzero (integral) ideals in a Dedekind domain \( D \). Show that if \( I \subseteq J \) then \( J^{-1} \subseteq I^{-1} \). Deduce that this is also the case for any pair of nonzero fractional ideals.
If \( R \subseteq S \) are commutative rings and \( I \) an ideal in \( R \), then we define an ideal \( SI \) in \( S \), the extension of \( I \) in \( S \), by letting \( SI \) be the collection of finite sums of the form \( \sum_{i=1}^m s_i x_i \), with \( s_i \in S \) and \( x_i \in I \). This is the smallest ideal in \( S \) containing \( I \) (or the ideal in \( S \) generated by \( I \)). We may generalize this idea to fractional ideals.

Let \( C \) be Dedekind domain and \( D \) a commutative ring containing \( D \). We note \( K \) the field of fractions of \( C \). If \( J \subseteq K \) is a fractional ideal of \( D \), then we write \( DJ \) for the collection of finite sums of the form \( \sum_{i=1}^m d_i x_i \), with \( d_i \in D \) and \( x_i \in J \). We claim that, if \( D \) is an integral domain, then \( DJ \) is a fractional ideal of \( D \). Indeed, \( DJ \) is clearly a \( D \)-module of the field of fractions of \( D \) and any denominator of \( J \) is a denominator of \( DJ \). This fractional ideal is the smallest fractional ideal of \( D \) containing \( J \).

If \( R \subseteq S \) are commutative rings and \( I \) an ideal in \( R \), then it is not necessarily the case that \( SI \cap R = I \). For example, if \( R = \mathbb{Z} \), \( S = \mathbb{Q} \) and \( I = (2) \), then \( SI = \mathbb{Z} \), because \( \mathbb{Q} \) is the only nonzero ideal in \( \mathbb{Q} \). As \( \mathbb{Q} \cap \mathbb{Z} = \mathbb{Z} \neq (2) \), in this case \( SI \cap R \neq I \). This example also shows that, even if \( R \) and \( S \) are Dedekind domains, it may not be true that \( SI \cap R = I \). The following result provides a framework where this property holds.

**Theorem 12.7** Let \( C \) be Dedekind domain, \( D \) a commutative ring containing \( C \) and \( K \) the field of fractions of \( C \). In addition, we suppose that \( C \cap D \subseteq K \).

- **a.** If \( J \) is a fractional ideal of \( C \), then \( DJ \cap K = J \);
- **b.** If \( I \) is an (integral) ideal of \( C \), then \( DI \cap C = I \).

**Proof.**

**a.** To begin with, \( DJ \cap K \) is always a fractional ideal of \( C \). Indeed, it is clearly a \( C \)-submodule of \( K \) and any denominator of \( J \) is a denominator of \( DJ \cap K \), because \( D \cap K \subseteq C \). If \( J = \{0\} \), then the result is evident, so suppose that this is not the case. Proposition 12.8 ensures that \( J \) has an inverse. Then

\[
D = DC = D(JJ^{-1}) = (DJ)(DJ^{-1}),
\]

hence

\[
C \supset D \cap K = ((DJ)(DJ^{-1})) \cap K \supset (DJ \cap K)(DJ^{-1} \cap K).
\]

Since \( DJ \cap K \) is a fractional ideal of \( C \), from Proposition 12.8 again, \( DJ \cap K \) has an inverse. We have

\[
C = (DJ \cap K)(DJ \cap K)^{-1} \implies (DJ \cap K)(DJ \cap K)^{-1} \supset (DJ \cap K)(DJ^{-1} \cap K).
\]

Now, using Exercise 12.5, we obtain

\[
(DJ \cap K)^{-1} \supset DJ^{-1} \cap K.
\]

Since \( J \subseteq DJ \cap K \), from Exercise 12.6,

\[
D(J^{-1}) \cap K \supset J^{-1} \supset (DJ \cap K)^{-1}
\]

and so

\[
(DJ \cap K)^{-1} = DJ^{-1} \cap K = J^{-1} \implies DJ \cap K = J,
\]

as required.
b. Let $I$ be an (integral) ideal in $C$. Since $I$ is also a fractional ideal, the part a. ensures that

$$DI \cap K = I.$$ 

Taking the intersection with $D$ on both sides leads to

$$DI \cap (K \cap D) = I.$$ 

Clearly $C \subset K \cap D$ and we have seen in part a. that $K \cap D \subset C$, so $K \cap D = C$ and it follows that $DI \cap C = I$. \qed

**Example** If $D$ is integral over $C$, then $D \cap K$ is included in the integral closure of $C$ in $K$. As $C$ is a normal domain, its integral closure in $K$, its field of fractions, is $C$ itself. Thus $D \cap K \subset C$ and so Theorem 12.7 applies.

If $R$ is an integral domain, then we may extend the equivalence relation defined in Section 12.3 to fractional ideals. In the same way as for the nonzero integral ideals, we define a relation $R$ on the nonzero fractional ideals of $R$ as follows: $IRJ$ if and only if there exist elements $\alpha, \beta \in R \setminus \{0\}$ such that $\alpha I = \beta J$. There is no difficulty in seeing that $R$ is an equivalence relation and so we write $\sim$ for $R$.

**Proposition 12.10** If $R$ is a Dedekind domain and $I$ is a nonzero fractional ideal in $R$, then there is a nonzero integral ideal $J$ such that $I \sim J$.

**Proof** Let $I$ be a nonzero fractional ideal. From the decomposition of fractional ideals we obtain the existence of integral ideals $B$ and $C$ such that $I = C/B$, with $C$ nontrivial. We take $t \in C$, with $t \neq 0$. Then $C \supset Rt \implies C|Rt$. Hence there exists an integral ideal $E \subset R$ such that $CE = Rt$. Therefore we have

$$(Rt)I = RtB/C = CEB/C = EB \implies tI = 1EB,$$

hence $I \sim EB$. \qed

**Remark** From the above proposition, every equivalence class contains an integral ideal.

### 12.6 Localization in a Dedekind domain

Before studying localization in a Dedekind domain, we will first revise (or introduce, for those not familiar with localization) the basic notions of localization in a commutative ring.

Let $R$ be a commutative ring. A subset $U$ of $R$ is said to be multiplicative if

- $1 \in U$;
- $x, y \in U \implies xy \in U$.

We define a relation $R$ on $R \times U$ by

$$(r, u)R(r', u'),$$

if there exists $t \in U$ such that

$$t(r'u' - r'u) = 0.$$
It is easy to show that $R$ is an equivalence relation, so we will write $\sim$ for $R$. Also, we write $\frac{r}{u}$ for the equivalence class of $(r, u)$. In general, we write $U^{-1}R$ for the collection of equivalence classes.

We may give $U^{-1}R$ a ring structure:

$$\frac{r}{u} + \frac{r'}{u'} = \frac{ru' + r'u}{uu'} \quad \text{and} \quad \frac{r}{u} \cdot \frac{r'}{u'} = \frac{rr'}{uu'}.$$  

It is easy to check that these operations are well-defined and that $U^{-1}R$ with these operations is a commutative ring. (The element $\frac{0}{1}$ (resp. $\frac{1}{1}$) is the identity for the addition (resp. multiplication).) The ring we have obtained is called the localization of $R$ with respect to $U$. Clearly, the procedure we have used generalizes the construction of the rational numbers, with $R = \mathbb{Z}$ and $U = \mathbb{Z}^\ast$.

**Exercise 12.7** Show that $U^{-1}R$ is a zero ring if and only if $0 \in U$.

From now on we suppose that $0 \notin U$.

**Exercise 12.8** Show that, if $R$ is an integral domain and $K$ its field of fractions, then the mapping

$$\phi : U^{-1}R \rightarrow K, \frac{r}{u} \mapsto \frac{r}{u}$$

is an injective ring homomorphism. It follows that, if $R$ is an integral domain, then so is $U^{-1}R$.

For a commutative ring $R$, the mapping

$$\pi : R \rightarrow U^{-1}R, r \mapsto \frac{r}{1}$$

is a ring homomorphism. In addition, if $u \in U$, then

$$\frac{u}{1} \cdot \frac{1}{u} = \frac{u}{u} = 1,$$

so the elements of $\pi(U)$ are invertible in $U^{-1}R$.

**Exercise 12.9** Show that the mapping $\pi$ defined above is injective if and only if $U$ has no zero divisors. It follows that, if $R$ is an integral domain, then $\pi$ is injective.

If $X$ is a subset of $R$, then we set

$$U^{-1}X = \{ \frac{x}{u} : x \in X, u \in U \}.$$  

Clearly, if $I$ is an ideal in $R$, then $U^{-1}I$ is an ideal in $U^{-1}R$. It is not difficult to see that $U^{-1}I$ is the collection of all finite sums of the form $\sum_{i=1}^n y_i \pi(x_i)$, where $y_i \in U^{-1}R$ and $x_i \in I$, which is the ideal in $U^{-1}R$ generated by $\pi(I)$. If $\pi$ is injective, then we may consider $I$ as a subset of $U^{-1}R$ and we write $(U^{-1}R)I$ for $U^{-1}I$.

**Remark** We may extend this idea. Suppose that $A$ and $B$ are commutative rings with identity and $f : A \rightarrow B$ a homomorphism. If $I$ is an ideal in $A$, then $f(I)$ is not necessarily an ideal in $B$, even if $f$ is injective (for example, the image of the ideal $2\mathbb{Z}$ in $\mathbb{Z}$ by inclusion of the ring of integers $\mathbb{Z}$ in the rationals $\mathbb{Q}$ is not an ideal in $\mathbb{Q}$.) However, if we let $I^e$ be the collection of all finite sums of the form $\sum_{i=1}^n y_i f(x_i)$, where $y_i \in B$ and $x_i \in I$, then $I^e$ is an ideal in $B$, called the extension of $I$ (under $f$) in $B$. $I^e$ is the ideal in $B$ generated by $f(I)$. If $f$ is an injection, then we write $BI$ for $I^e$.
Lemma 12.5  Let $I$ be an ideal in $R$. Then $U^{-1}I$ is a proper ideal in $U^{-1}R$ if and only if $I \cap U = \emptyset$.

Proof  If $u \in I \cap U$, then $\frac{1}{u} = \frac{1}{u} \in U^{-1}I$, so $U^{-1}I$ is not a proper ideal. On the other hand, if $U^{-1}I = U^{-1}R$, then $\frac{1}{u} = \frac{1}{u}$, for some $r \in I$ and $u \in U$, hence there exists $t \in U$ such that

$$t(u - r) = 0 \implies tu = tr.$$ 

However, $tu \in U$, because $t,u \in U$, and $tr \in I$, because $r \in I$, so $I \cap U \neq \emptyset$. \hfill \Box

The next result is elementary, but important.

Proposition 12.11  If $I$ and $J$ are ideals in $R$, then

- a. $U^{-1}(I + J) = U^{-1}I + U^{-1}J$;
- b. $U^{-1}(I \cap J) = U^{-1}I \cap U^{-1}J$;
- c. $U^{-1}(IJ) = (U^{-1}I)(U^{-1}J)$.

Proof  It is clear that in all three cases the lefthand side is contained in the righthand side, so we only need to show that the righthand side is included in the lefthand side.

a. If $\frac{r}{u} \in U^{-1}I$ and $\frac{r'}{u'} \in U^{-1}J$, then

$$\frac{r}{u} + \frac{r'}{u'} = \frac{ru' + r'u}{uu'} \in U^{-1}(I + J),$$

because $ru' \in I$ and $r'u \in J$. Thus

$$U^{-1}I + U^{-1}J \subset U^{-1}(I + J).$$

b. If $\frac{r}{u} \in U^{-1}I \cap U^{-1}J$, then there exist $r_1 \in I$, $u_1 \in U$ and $t_1 \in U$ such that

$$t_1(ru_1 - r_1u) = 0 \implies t_1ru_1 = t_1r_1u \in I$$

and $r_2 \in J$, $u_2 \in U$ and $t_2 \in U$ such that

$$t_2(ru_2 - r_2u) = 0 \implies t_2ru_2 = t_2r_2u \in J.$$ 

It follows that

$$t_1t_2ru_1u_2 \in I \cap J.$$ 

Thus there exists $\bar{u} \in U$ such that $r\bar{u} \in I \cap J$. Now $\frac{r}{u} = \frac{r\bar{u}}{u\bar{u}} \in U^{-1}(I \cap J)$, so

$$U^{-1}I \cap U^{-1}J \subset U^{-1}(I \cap J).$$

c. Let $\frac{r_1}{u_1}, \ldots, \frac{r_n}{u_n} \in U^{-1}I$ and $\frac{r'_1}{u'_1}, \ldots, \frac{r'_n}{u'_n} \in U^{-1}J$. Then

$$\frac{r_1 r'_1}{u_1 u'_1} + \cdots + \frac{r_n r'_n}{u_n u'_n} = \frac{r}{u_1 u'_1 \cdots u_n u'_n},$$

where $r \in IJ$, so

$$(U^{-1}I)(U^{-1}J) \subset U^{-1}(IJ).$$

150
This ends the proof.

Above we introduced the mapping
\[ \pi : R \rightarrow U^{-1}R, r \mapsto \frac{r}{1}. \]

As \( \pi \) is a ring homomorphism, if \( J \) is an ideal in \( U^{-1}R \), then \( \pi^{-1}(J) \) is an ideal in \( R \). Also, we have seen that, if \( I \) is an ideal in \( R \), then \( U^{-1}I \) is an ideal in \( U^{-1}R \). It follows that \( U^{-1}(\pi^{-1}(J)) \) is an ideal in \( U^{-1}R \). In fact, we have a stronger result.

**Proposition 12.12** If \( J \) is an ideal in \( U^{-1}R \), then
\[ U^{-1}(\pi^{-1}(J)) = J. \]

**Proof** If \( \frac{r}{u} \in U^{-1}(\pi^{-1}(J)) \), then there exist \( r' \in \pi^{-1}(J) \), \( u' \in U \) and \( t \in U \) such that
\[ t(ru' - r'u) = 0 \implies tru' = tur' \in \pi^{-1}(J) \implies \frac{tru'}{1} \in J. \]

Therefore
\[ \frac{r}{u} = \frac{tru'}{tua'} = \frac{tru'}{1} \cdot \frac{1}{tua'} \in J. \]

Hence
\[ U^{-1}(\pi^{-1}(J)) \subset J. \]

To prove the converse, let us take \( \frac{r}{u} \in J \). Then
\[ \frac{r}{1} = \frac{r}{u} \cdot \frac{u}{1} \in J \implies r \in \pi^{-1}(J) \implies \frac{r}{u} \in U^{-1}(\pi^{-1}(J)). \]

Thus
\[ J \subset U^{-1}(\pi^{-1}(J)). \]

This completes the proof.

Let us write \( \mathcal{I}_R \) (resp. \( \mathcal{I}_{U^{-1}R} \)) for the collection of ideals in \( R \) (resp. \( U^{-1}R \)).

**Proposition 12.13** The mapping
\[ \pi^{-1} : \mathcal{I}_{U^{-1}R} \rightarrow \mathcal{I}_R, J \mapsto \pi^{-1}(J) \]
is injective.

**Proof** If \( \pi^{-1}(J_1) = \pi^{-1}(J_2) \), then from Proposition 12.12 we have
\[ J_1 = U^{-1}(\pi^{-1}(J_1)) = U^{-1}(\pi^{-1}(J_2)) = J_2 \]
and the injectivity follows.

The main object of this section is to show that the localization of a Dedekind domain is a Dedekind domain. We have already observed that the localization of an integral domain \( D \) is an integral domain (Exercise 12.8). We now show that the noetherian property carries over to a localization.
Proposition 12.14 If $R$ is a noetherian ring and $U$ a multiplicative subset of $R$, then the localization $U^{-1}R$ is a noetherian ring.

Proof Let $\pi : R \to U^{-1}R$ be the standard ring homomorphism taking $r$ to $\frac{r}{1}$. We take an ascending sequence of ideals in $U^{-1}R$: $J_0 \subset J_1 \subset J_2 \subset \cdots$

The inverse images under $\pi$ of these ideals form an ascending chain of ideals in $R$: $\pi^{-1}(J_0) \subset \pi^{-1}(J_1) \subset \pi^{-1}(J_2) \subset \cdots$

As $R$ is noetherian, this chain eventually stabilizes, i.e., there exists $k$ such that $\pi^{-1}(J_k) = \pi^{-1}(J_{k+1}) = \cdots$

However, the mapping $\pi^{-1}$ is injective (Proposition 12.13), so we have $J_k = J_{k+1} = \cdots$

and it follows that $U^{-1}R$ is noetherian. $\square$

Our next step is to show that

Proposition 12.15 If $R$ is a normal domain and $0 \notin U$, then $U^{-1}R$ is a normal domain.

Proof Let $\alpha$ be an element of the fraction field of $U^{-1}R$ which is integral over $U^{-1}R$, i.e., there exists a polynomial $f(X) = \sum_{i=0}^{k-1} a_i X^i + X^k \in U^{-1}R[X]$ such that $f(\alpha) = 0$. We take $u \in U$ such that $u$ is a multiple of the denominators of the $a_i$, then $ua_0, ua_1, \ldots, ua_{k-1} \in R$. Setting $\tilde{f}(X) = \sum_{i=0}^{k-1} u^{k-i} a_i X^i + X^k$, we have $f \in R[X]$ and $\tilde{f}(u) = 0$, so $ua$ is integral over $R$. We may also choose $u$ such that $ua$ lies in the field of fractions of $R$. To see this, notice that

$$\frac{r_1}{u_1} \frac{r_2}{u_2} \Rightarrow u\alpha = \frac{r_1}{u_1} \frac{r_2}{u_2} = \frac{ur_1u_2}{u_1u_2}.$$ 

If we choose $u \in U$ to be a multiple of $u_1$, then $ua$ belongs to the field of fractions of $R$. As $R$ is a normal domain, $ua \in R$, which implies that $\alpha = \frac{ua}{u} \in U^{-1}R$. It follows that $U^{-1}R$ is a normal domain. $\square$

To show that $U^{-1}D$ is a Dedekind domain if $D$ is a Dedekind domain we must show that prime ideals are maximal. To do so, we first consider the mapping $\pi^{-1}$ restricted to prime ideals.

Lemma 12.6 If $I$ is an ideal in $R$, then

$$I \subset \pi^{-1}(U^{-1}I),$$

with equality if $I$ is a prime ideal disjoint from $U$.

Proof If $r \in I$, then $\frac{r}{1} \in U^{-1}I$, hence $r \in \pi^{-1}(U^{-1}I)$. This proves the first part of the lemma.

Now suppose that $I$ is a prime ideal in $R$ such that $I \cap U = \emptyset$ and let $r \in \pi^{-1}(U^{-1}I)$. Then $\pi(r) = \frac{r}{1} \in U^{-1}I$, so $\frac{r}{1} = \frac{s}{t}'$, for some $s' \in I$ and $u' \in U$. Thus there exists $t \in U$ such that

$$t(ru' - r') = 0 \Rightarrow tru' = tr',$$

with $tu' \notin I$, because $U \cap I = \emptyset$. (If $tu' \notin I$, then $t \in I$ or $u' \in I$, a contradiction.) Since $tr' \in I$, also $tru' \in I$. Given that $tu' \notin I$ and $I$ is prime, we must have $r \in I$. Hence $\pi^{-1}(U^{-1}I) \subset I$. $\square$

We will write $\mathcal{P}_{U^{-1}R}$ for the set of prime ideals in $U^{-1}R$ and $\mathcal{P}_{R^U}$ for the set of prime ideals in $R$ disjoint from $U$. 

152
Theorem 12.8 The mapping $\pi^{-1}$ restricted to $P_{U^{-1}R}$ defines a bijection onto $P_{R\setminus U}$.

Proof We have already observed that, if $J$ is an ideal in $U^{-1}R$, then $\pi^{-1}(J)$ is an ideal in $R$ and that the mapping $\pi^{-1}$ is injective (Proposition 12.13). It is elementary to show that $\pi^{-1}(J)$ is prime when $J$ is prime. We must show that $\pi^{-1}(J) \cap U = \emptyset$. From Lemma 12.5 and Proposition 12.12

$$\pi^{-1}(J) \cap U = \emptyset \iff U^{-1}\pi^{-1}(J) \neq U^{-1}R \iff J \neq U^{-1}R.$$  

Since $J$ is a prime ideal of $U^{-1}R$, $J \neq U^{-1}R$, so $\pi^{-1}(J) \cap U = \emptyset$, as desired. We have shown that the image of $\pi^{-1}$ restricted to $P_{U^{-1}R}$ lies in $P_{R\setminus U}$.

To finish we only need to show that $\pi^{-1}(P_{U^{-1}R}) = P_{R\setminus U}$. Let $I \in P_{R\setminus U}$. From Lemma 12.6 we have

$$I = \pi^{-1}(U^{-1}I).$$

As $I$ is a prime ideal in $R$ and $I \cap U = \emptyset$, $U^{-1}I$ is a prime ideal in $U^{-1}R$, so $\pi^{-1}$ restricted to $P_{U^{-1}R}$ is surjective. \qed

Corollary 12.10 If $R$ is a commutative ring in which every nonzero prime ideal is maximal, then this is also the case for the localization $U^{-1}R$.

Proof Let $J$ be a nonzero prime ideal in $U^{-1}R$ which is not maximal. Then there exists a nonzero prime ideal $J'$ in $U^{-1}R$ which properly contains $J$. From the previous theorem, both $\pi^{-1}(J)$ and $\pi^{-1}(J')$ are nonzero prime ideals and $\pi^{-1}(J)$ is properly contained in $\pi^{-1}(J')$. However, this is a contradiction, because $\pi^{-1}(J)$ must be maximal. Hence $J$ is maximal. \qed

Exercise 12.10 If $I$ is a prime ideal in $R$ and $I \cap U \neq \emptyset$, show that $U^{-1}I$ is not a prime ideal in $U^{-1}R$.

We are now in a position to establish the main theorem of this section.

Theorem 12.9 If $D$ is a Dedekind domain and $U$ a multiplicative subset of $D$ not containing 0, then $U^{-1}D$ is a Dedekind domain.

Proof We noticed in Exercise 12.11 that if the multiplicative set $U$ has no zero divisors, then $U^{-1}R$ is an integral domain. Since $D$ is an integral domain, so is $U^{-1}D$. Next, from Proposition 12.14, $U^{-1}D$ is a noetherian ring. Now, using Proposition 12.18, we see that $U^{-1}D$ is a normal domain. To finish we only need to show that every nonzero prime ideal in $U^{-1}D$ is maximal. However, this follows from Corollary 12.10. \qed

Suppose now that $I$ is an ideal in $D$ such that $I \neq \{0\}$, $D$ and $I = \prod\limits_{1}^{r} \mathfrak{P}^{e_{i}}$ is the decomposition of $I$ into prime ideals of $D$. In the Dedekind domain $D' = U^{-1}D$ the ideal $J$ generated by $I$ has a decomposition into prime ideals of $D'$. The following proposition gives us the form of this decomposition.

Proposition 12.16 Let $I$ be an ideal of the Dedekind domain $D$, such that $I \neq \{0\}$, $D$, and $U$ a multiplicative subset of $D$ not containing 0. If $I = \prod\limits_{1}^{r} \mathfrak{P}^{e_{i}}$ is the decomposition of $I$ into prime ideals of $D$ and $J$ the ideal in $D' = U^{-1}D$ generated by $I$, then the decomposition of $J$ into prime ideals has the form

$$J = \prod\limits_{\mathfrak{P} \cap U = \emptyset}^{\infty} (D')^{e_{i}} = 0.$$
Proof First we have
\[ J = D'I = D' \left( \prod_{i=1}^{r} P_i^e_i \right) = \prod_{i=1}^{r} (D'P_i)^{e_i}. \]
If \( P_i \cap U \neq \emptyset \) then \( D'P_i \) contains a unit, so \( D'P_i = D' \). Thus
\[ J = \prod_{P_i \cap U = \emptyset} (D'P_i)^{e_i}. \]
It remains to show that \( D'P_i \) is a prime ideal if \( P_i \cap U = \emptyset \). Let \( \frac{a}{u}, \frac{b}{v} \in D' \) be such that \( \frac{a}{u}, \frac{b}{v} \in D'P_i \). Then \( \frac{a}{u} \cdot \frac{b}{v} = \frac{w}{x} \), with \( x \in P_i \) and \( w \in U \). So \( abw = wvx \in P_i \), because \( x \in P_i \). Given that \( w \notin P_i \), because \( P_i \cap U = \emptyset \), we have \( ab \in P_i \), which implies that \( a \in P_i \) or \( b \in P_i \). Hence \( \frac{a}{u} \in D'P_i \) or \( \frac{b}{v} \in D'P_i \), which shows that \( D'P_i \) is a prime ideal.

A special case

If a commutative ring has a unique maximal ideal, then we say that it is a local ring. In certain cases the localization of a commutative ring is a local ring. We will be particularly interested in the case where the ring is a Dedekind domain. However, we will first present a result giving two characterizations of local rings.

**Proposition 12.17** The following conditions are equivalent for a commutative ring \( R \):

a. \( R \) is a local ring;

b. There is a proper ideal \( I \) of \( R \) which contains all the nonunits of \( R \);

c. The set of nonunits of \( R \) is an ideal.

Proof

a. \( \Rightarrow \) b. If \( r \) is a nonunit, then \( (r) \) is a proper ideal in \( R \) and so is contained in the unique maximal ideal of \( R \).

b. \( \Rightarrow \) c. Let \( A \) be the collection of nonunits in \( R \). If \( r, r' \in A \) and \( x \in R \), then \( r + r' \) and \( xr \) are in \( A \). If not, then there exists \( a \in R \) such that \( a(r + r') = 1 \), or \( b \in R \) such that \( b(xr) = 1 \). In both cases, \( 1 \in A \subset I \) and so \( I = R \), a contradiction. Hence \( A \) is a proper ideal in \( R \).

c. \( \Rightarrow \) a. If \( I \) is the ideal of nonunits, then \( I \) is maximal. If not, then there is an ideal \( I' \neq R \) which properly contains \( I \). As \( I' \) must contain a unit, \( I' = R \). It follows that \( I \) is maximal. If \( H \) is a proper ideal in \( R \), then \( H \) cannot contain a unit, so \( H \subset I \). Therefore \( I \) is the unique maximal ideal.

**Exercise 12.11** Show that the unique maximal ideal of a local ring is composed of its nonunits.

If \( P \) is a prime ideal in the commutative ring \( R \), then \( U = R \setminus P \) is a multiplicatve subset of \( R \) and \( 0 \notin U \). We write \( R_P \) for the localization \( (R \setminus P)^{-1}R \). We call \( R_P \) the localization of \( R \) at \( P \). The expression \( X \cap R \setminus P = \emptyset \), for \( X \subset R \), is equivalent to \( X \subset P \). We also notice that \( R \setminus P \) has no zero divisors, so from Exercise 12.11 the mapping \( \pi : R \rightarrow R_P \) is injective.

**Theorem 12.10** If \( R \) is a commutative ring and \( P \) a prime ideal in \( R \), then the localization \( R_P \) is a local ring, with unique maximal ideal

\[ (R \setminus P)^{-1}P = \{ \frac{x}{u} \mid x \in P, u \in R \setminus P \}. \]
proof} As $P \cap R \setminus P = \emptyset$, from Lemma 12.5, $(R \setminus P)^{-1}P$ is a proper ideal in $R_P$. Let $J$ be a maximal ideal in $R_P$. As $J$ is prime, $\pi^{-1}(J)$ is a prime ideal in $R$, which is disjoint from $R \setminus P$ by Theorem 12.8. As observed above, $\pi^{-1}(J) \cap (R \setminus P) = \emptyset$ is equivalent to $\pi^{-1}(J) \subset P$, since $\pi^{-1}(J) \subset R$. Then, by Proposition 12.12,

$$J = (R \setminus P)^{-1}(\pi^{-1}(J)) \subset (R \setminus P)^{-1}P.$$  

Since $J$ is a maximal ideal in $R_P$ and $(R \setminus P)^{-1}P$ is a proper ideal in $R_P$, we have $J = (R \setminus P)^{-1}P$. It follows that $(R \setminus P)^{-1}P$ is the unique maximal ideal of $R_P$. \hfill \square

In accordance with the discussion after Exercise 12.11, for an ideal $I$ in $R$, $(R \setminus P)^{-1}I = R_PI$, i.e., $(R \setminus P)^{-1}I$ is composed of finite sums of the form

$$x = \sum_{i=1}^{n} y_i \pi(x_i),$$

where $y_i \in R_P$ and $x_i \in I$. In particular, the unique maximal ideal of $R_P$ can be written $R_PP$.

Now let us now consider the particular case of the localization of a Dedekind domain $D$ at a prime ideal $P$.

**Theorem 12.11** If $D$ is a Dedekind domain and $P$ a prime ideal in $D$, then the localization $D_P$ is a PID.

**proof** From Theorem 12.9, $D_P$ is a Dedekind domain. By Theorem 12.10, $D_P$ is also a local ring and so has a unique ideal. However, a Dedekind domain having only a finite number of prime ideals is a PID (Corollary 12.7), hence the result. \hfill \square

We may characterize the nonzero fractional ideals of $D_P$; however, we need to do some preliminary work. We recall that in Proposition 12.11 we showed that if $U$ is a multiplicative subset of the ring $R$, and $I$ and $J$ ideals, then

$$U^{-1}(IJ) = (U^{-1}I)(U^{-1}J).$$

If $R$ is an integral domain, $P$ a prime ideal of $R$ and $U = R \setminus P$, then we obtain

$$R_P(IJ) = (R_PI)(R_PJ). \tag{12.2}$$

We aim to extend this relation to fractional ideals of $R$. First we extend the definition $R_PI$ to fractional ideals. For a fractional ideal $F$ of $R$ we let $R_PF$ be the subset of the fraction field $K$ of $R_P$ composed of finite sums of the form

$$x = \sum_{j=1}^{n} f_j x_j,$$

where $i_j \in I$, $x_j \in R_P$. (If $f \in F$, then $f = \frac{r}{r'}$, with $r \in R$, $r' \in R^*$; then $fx = \frac{rx}{r'} \in K$ and it follows that $R_PF \subset K$.) In fact, $R_PF$ is a fractional ideal of $R_P$. If $F$ is the zero ideal, then there is nothing to prove, so let us suppose that this is not the case. Then $F = \alpha I$, where $\alpha \in R^*$ and $I$ an ideal of $R$ (Proposition 12.6). If $f \in F$ and $x \in R_P$, then $fx = \alpha f sx$, where $s \in I$. It follows that $R_PF = \alpha R_PI$. As $R_PI$ is an ideal in $R_P$, another application of Proposition 12.6 shows that $R_PF$ is a fractional ideal of $R_P$.

We may now extend Equation (12.2) to fractional ideals.
Proposition 12.18 If $R$ is an integral domain, $P$ a prime ideal in $R$ and $F$, $G$ fractional ideals, then 

**Proof** An element of $R_P(FG)$ can be written in the form $x \sum_{i=1}^n f_i g_i$, where $f_i \in F$, $g_i \in G$ and $x \in R_P$. Since $x = \frac{u}{v}$, with $r \in R$ and $u \in R \setminus P$, we have

$$x \sum_{i=1}^n f_i g_i = \sum_{i=1}^n \left( \frac{r}{1} f_i \left( \frac{1}{u} g_i \right) \right) \in R_P(F)R_P(G),$$

Hence $R_P(FG) \subseteq (R_P F)(R_P G)$.

Moreover, any element of $(R_P F)(R_P G)$ is a finite sum of terms of the form $(xf)(yg)$, where $x, y \in R_P$ and $f \in F$, $g \in G$. However, $(xf)(yg) = (xy)(fg)$. Given that $xy \in R_P$ and $fg \in FG$, $(xf)(yg) \in R_P(FG)$ and it follows that $(R_P F)(R_P G) \subseteq R_P(FG)$. 

We are now in position to establish a result which will prove essential further on. It provides us with a characterization of the nonzero fractional ideals of the localization of a Dedekind domain at a prime ideal.

Theorem 12.12 If $D$ is a Dedekind domain and $P$ a nonzero prime ideal in $D$, then every nonzero fractional ideal $J$ of $D_P$ is a power of $D_P P$ and, for any $m \in \mathbb{Z}$, $(D_P P)^m = D_P P^m$. In addition, for any $m \geq 0$, $D_P(P^m) \cap D = P^m$.

**Proof** Theorem 12.9 ensures that $D_P$ is a Dedekind domain and Theorem 12.10 that $D_P$ has a unique prime ideal, namely $D_P$. Now, using Theorem 12.6, we obtain that every nonzero fractional ideal $J$ of $D_P$ is a power of $D_P P$: $J = (D_P P)^m$, for some $m \in \mathbb{Z}$. If $m = 0$, then $J = D_P$.

Let us now show that $(D_P P)^m = D_P (P^m)$. We will consider three cases, namely, $m = 0$, $m \geq 1$ and $m \leq -1$.

**Case 1:** $m = 0$. For $m = 0$, this amounts to showing that $D_P = D_P D$. Clearly, $D_P D \subseteq D_P$. If $\frac{a}{b} \in D_P$, then $\frac{a}{b} = \frac{a}{b} \cdot 1 \in D_P D$, so $D_P \subseteq D_P D$ and we have the desired equality.

**Case 2:** $m \geq 1$. For $m \geq 1$ we use an induction argument. For $m = 1$, there is nothing to prove. For $m \geq 2$, it is sufficient to apply Proposition 12.18.

**Case 3:** $m \leq -1$. From Proposition 12.18 we have

$$D_P = D_P D = D_P (P P^{-1}) = (D_P P)(D_P P^{-1}) \implies D_P P^{-1} = (D_P P)^{-1}.$$ 

If $m \leq -2$, let us set $n = -m$. Then, using Proposition 12.18 again, we have

$$D_P P^m = D_P ((P^{-1})^{-m}) = (D_P P^{-1})^{-m}.$$ 

However, $D_P P^{-1} = (D_P P)^{-1}$, so

$$(D_P P^{-1})^{-m} = ((D_P P)^{-1})^{-m} = (D_P P)^m.$$ 

We now turn to the final part of the theorem. Let $m \geq 1$. It is clear that $P^m \subseteq D_P P^m \cap D$. Suppose now that $\frac{a}{b} \in D_P P^m \cap D$, with $x \in P^m$ and $u \notin P$. There exists $r \in D$ such that
$\xi = \frac{r}{u}$. This implies that there is a $t \notin P$ such that $t(x - ru) = 0$. Hence we have $tru = tx \in P^m$, with $tu \notin P$. As $tru \in P^m$, $P^m$ contains the product of the principal ideals $Dtu$ and $Dr$. This means that $P^m$ divides $DtuDr$. As $tu \notin P$, $P$ does not divide $Dtu$. Since $P$ is a prime ideal, $P^m$ divides $Dr$, which implies that $r \in P^m$. Thus $\frac{r}{u} = \frac{t}{x}$, with $r \in P^m$. Therefore $D_PM \cap D \subset P^m$. This ends the proof.

**Quotient rings of localizations**

If $I$ is a proper ideal in $R$, then we have a canonical homomorphism $\lambda$ of $R$ onto the quotient ring $\bar{R} = R/I$. A multiplicative subset $U$ of $R$ induces in a natural way a multiplicative subset of $\bar{R} = R/I$, namely $\bar{U} = \lambda(U)$. The following proposition characterizes the localization of $\bar{R}$ with respect to $\bar{U}$.

**Proposition 12.19** Let $U$ be a multiplicative subset of the ring $R$ and $R' = U^{-1}R$. If $I$ is a proper ideal in $R$ such that $ru \in I, r \in R, u \in U \implies r \in I$, then the image $\bar{U}$ of $U$ under $\lambda$ is a multiplicative subset of $\bar{R}$ with no zero divisors, and $\bar{U}^{-1}\bar{R}$ is isomorphic to $R'/R'I$.

**Proof** First we notice that $I \cap U = \emptyset$: If $a \in I \cap U$, then $a1 \in I$ and so, by hypothesis, $1 \in I$, which is impossible, because $I$ is a proper ideal of $R$.

To see that $\bar{U}$ is a multiplicative subset of $\bar{R}$, first we notice that $1 \in U$ implies that $1 \in \bar{U}$. Next, if $\bar{a}, \bar{b} \in \bar{U}$, then $\bar{a} = a + I$, with $a \in U$, and $\bar{b} = b + I$, with $b \in U$, hence $\bar{a}\bar{b} = ab + I \in \bar{U}$, because $ab \in U$.

Finally we show that $\bar{U}$ has no zero divisors. Let $\bar{a} \in \bar{U}$. If $\bar{ab} = 0$, with $b \in R/I$, then $ab \in I$. As $a \in U$, by hypothesis $b \in I$, so $b = 0$. Therefore $\bar{U}$ has no zero divisors.

We now define a mapping $\psi$ from $\bar{U}^{-1}\bar{R}$ into $R'/R'I$ by

$$\psi(\frac{\bar{r}}{u}) = \frac{\bar{r}_1}{u_1},$$

where $\frac{\bar{r}}{u}$ is the image of $\frac{r}{u}$ under the canonical homomorphism of $R'$ onto $\bar{R}$. We need to show that $\psi$ is well-defined, i.e.,

$$\frac{\bar{r}}{u} = \frac{\bar{r}_1}{u_1} \implies \frac{\bar{r}}{u} = \frac{\bar{r}_1}{u_1}.$$

Indeed, if there exists $\bar{t} \in \bar{U}$ such that

$$\bar{t}(\bar{r}\bar{u}_1 - \bar{r}_1\bar{u}) = \bar{0},$$

then

$$(ru_1 - r_1u)t \in I \implies ru_1 - r_1u \in I \implies \frac{r}{u} = \frac{r_1}{u_1} = \frac{ru_1 - r_1u}{wu_1} \in R'I,$$

where in the first implication we have used the hypothesis on $I$. Thus $\frac{\bar{r}}{u} = \frac{\bar{r}_1}{u_1}$ and the mapping $\psi$ is well-defined.

Clearly, $\psi$ is a ring homomorphism. If $x \in \bar{R}'$, then $x = \frac{\bar{r}}{u} + R'I$, with $r \in R, u \in U$. If we set $y = \frac{r}{u}$, then $\bar{r} \in \bar{R}, \bar{u} \in \bar{U}$ and $\psi(y) = x$. Thus $\psi$ is surjective. If $\frac{\bar{r}}{u} = 0$, then $\bar{r} \in R'I$. Then $\frac{\bar{r}}{u} = \frac{\bar{r}'}{u'}$, with $r' \in I$ and $u' \in U$. Hence there exists $t \in U$ such that $t(ru' - r'u) = 0$ and so $tru' \in I$. As $tu' \in U$, by hypothesis $r \in I$ and it follows that $\frac{r}{u} = 0$ in $\bar{U}^{-1}\bar{R}$, so $\psi$ is injective.

This ends the proof. \qed
The next result characterizes the residue field of the localization of a commutative ring with respect to a maximal ideal.

**Corollary 12.11** If all the elements of $\hat{U}$ are invertible in $\hat{R}$, then $\hat{R}$ is isomorphic to $R'/R'I$.

If $P$ is a maximal ideal in a commutative ring $R$, then $R/P$ is isomorphic to $R_P/R_P P$.

**Proof** Suppose that all the elements of $\hat{U}$ are invertible in $\hat{R}$. If $\frac{r}{u} \in \hat{U}^{-1}\hat{R}$ and we set $\frac{r_1}{u} = \frac{ru}{u}$, then $\frac{r}{u} = \frac{r_1}{u}$, so the canonical mapping from $\hat{R}$ into $\hat{U}^{-1}\hat{R}$ is an isomorphism. Thus we have an isomorphism from $\hat{R}$ onto $R'/R'I$.

Let us set $U = R \setminus P$. If $ru \in P$, with $r \in R$ and $u \in U$, then $r \in P$, because $P$ is a prime ideal. Hence we can apply Proposition 12.19 with $I = P$: $\hat{U}^{-1}(R/P)$ is isomorphic to $R_P/R_P P$. Because $R/P$ is a field, every element of $\hat{U}$ is invertible. It follows that there is an isomorphism from $R/P$ onto $R_P/R_P P$. \hfill $\square$

**Localization and integral closure**

If $U$ is a multiplicative subset of a ring $R$, and $S$ a ring containing $R$, then $U$ is also a multiplicative subset of $S$. We aim to consider the case where $L$ is some field containing $R$ and $S$ the integral closure of $R$ in $L$. Thus the set $U^{-1}S$ is defined. However, if $R' = U^{-1}R$ is also contained in $L$, then integral closure of $R'$ in $L$ also exists.

**Proposition 12.20** Let $R$ be an integral domain and $L$ a field containing $R$. We suppose that $S$ is the integral closure of $R$ in $L$ and that $U$ is a multiplicative subset of $R$. Then $S' = U^{-1}S$ is the integral closure of $R' = U^{-1}R$ in $L$.

**Proof** As $R' \subset K$, the field of fractions of $R$, and $K \subset L$, the integral closure of $R'$ in $L$ exists.

Let $x = \frac{r}{u} \in S'$. As $S$ is integral over $R$, there exist $r_0, r_1, \ldots, r_{n-1} \in R$ such that

$$r_0 + r_1 s + \cdots + r_{n-1} s^{n-1} + s^n = 0 \implies \frac{1}{u^n}(r_0 + r_1 s + \cdots + r_{n-1} s^{n-1} + s^n) = 0.$$ 

This can be written

$$\frac{r_0}{u^n} + \frac{r_1}{u^{n-1}} \frac{s}{u} + \cdots + \frac{r_{n-1}}{u^{n-1}} \frac{s^{n-1}}{u} + \frac{s^n}{u^n} = 0,$$

which implies that $\frac{r}{u}$ is integral over $R'$.

Now let $x \in L$ be integral over $S'$. There exist $\frac{r_0}{u_0}, \frac{r_1}{u_1}, \ldots, \frac{r_{n-1}}{u_{n-1}} \in S'$ such that

$$\frac{r_0}{u_0} + \frac{r_1}{u_1} x + \cdots + \frac{r_{n-1}}{u_{n-1}} x^{n-1} + x^n = 0.$$

Setting $u = u_0u_1 \cdots u_{n-1}$, we may write

$$u^n \left( \frac{r_0}{u_0} + \frac{r_1}{u_1} x + \cdots + \frac{r_{n-1}}{u_{n-1}} x^{n-1} + x^n \right) = 0.$$ 

However,

$$u^n r_i x^i = \frac{u^{n-1} r_i}{u_i} (ux)^i \quad \text{with} \quad \frac{u^{n-1} r_i}{u_i} \in R,$$

so $ux$ is integral over $R$. As the integral closure of $R$ in $L$ is $S$, we have $ux \in S$, which implies that $x = \frac{ux}{u} \in U^{-1}S$. \hfill $\square$

**Remark** We may sum up the proposition by saying that localization of the integral closure is the same as the integral closure of the localization, i.e., the operations integral closure and localization commute.
12.7 Integral closures of Dedekind domains

If \( D \) is a Dedekind domain, then certain extensions of \( D \) are also Dedekind domains. We have seen that this is in general the case with localizations. In this section we aim to consider another class of such extensions. The properties of such extensions enable us to establish certain important results.

**Lemma 12.7** Let \( A \subset B \subset C \) be commutative rings. If \( B \) is a finitely generated \( A \)-module and \( C \) a finitely generated \( B \)-module, then \( C \) is a finitely generated \( A \)-module.

**Proof** Let \( \{b_1, \ldots, b_m\} \) be a generating set for \( B \) over \( A \) and \( \{c_1, \ldots, c_n\} \) a generating set for \( C \) over \( B \). For \( x \in C \), there are \( \beta_1, \ldots, \beta_n \in B \) such that

\[
x = \sum_{i=1}^{n} \beta_i c_i.
\]

For any \( i = 1, \ldots, n \), there exist \( \alpha_{i1}, \ldots, \alpha_{im} \in A \) such that

\[
\beta_i = \sum_{j=1}^{m} \alpha_{ij} b_j,
\]

hence

\[
x = \sum_{i=1}^{n} \left( \sum_{j=1}^{m} \alpha_{ij} b_j \right) c_i = \sum_{i=1}^{n} \sum_{j=1}^{m} \alpha_{ij} (b_j c_i).
\]

As \( B \subset C \), the elements \( b_j c_i \) belong to \( C \) and it follows that the \( b_j c_i \), for \( 1 \leq j \leq m \) and \( 1 \leq i \leq n \), form a generating set for \( C \) over \( A \).

\[\square\]

**Theorem 12.13** (transitivity of integrality) Let \( A \subset B \subset C \) be commutative rings. If \( B \) is integral over \( A \) and \( C \) integral over \( B \), then \( C \) is integral over \( A \).

**Proof** Let \( x \in C \). As \( C \) is integral over \( B \), there exist \( b_0, b_1, \ldots, b_{n-1} \in B \) such that

\[
b_0 + b_1 x + \cdots + b_{n-1} x^{n-1} + x^n = 0.
\]  \( \tag{12.3} \)

We set \( D = A[b_0, b_1, \ldots, b_{n-1}] \) and \( E = D[x] \). From equation (12.3), powers of \( x \) higher than \( n - 1 \) can be expressed as a linear sum of powers of \( x \) (with coefficients in \( D \)) smaller than \( n \). Hence \( E \) is a finitely generated \( D \)-module. In the same way, as \( B \) is integral over \( A \), for each \( b_i \), there is a positive integer \( m_i \) such that powers of \( b_i \) higher than \( m_i - 1 \) can be expressed as a linear sum of powers of \( b_i \) (with coefficients in \( A \)) smaller than \( m_i \). As \( D \) is composed of finite sums of \( b_i \), \( C \) is integral over \( A \). It follows that \( C \) is integral over \( A \). \( \square \)

**Corollary 12.12** Let \( S \subset R \) be commutative rings and \( C \) the integral closure of \( S \) in \( R \). Then \( C \) is integrally closed in \( R \).

The intersection of all subrings of \( R \) which contain \( S \) and integrally closed in \( R \) is the integral closure \( C \) of \( S \) in \( R \).
PROOF Let \( x \in R \) be integral over \( C \). From Theorem 12.13 we deduce that \( C[x] \) is integral over \( S \). In particular, \( x \) is integral over \( S \), so \( x \in C \).

Suppose now that \( S \subset T \subset R \) are commutative rings, where \( T \) is integrally closed in \( R \). Let \( x \in C \). Then \( x \) is a zero of a monic polynomial with coefficients in \( S \). As \( S \subset T \), \( x \) is also a zero of a monic polynomial with coefficients in \( T \). Given that \( T \) is integrally closed, \( x \in T \). Thus \( C \subset T \) and the result now follows. \( \square \)

We have a second corollary.

Corollary 12.13 If \( K \subset L \) are number fields, then \( O_L \) is the integral closure of \( O_K \) in \( L \).

PROOF Let \( A \) be the integral closure of \( O_K \) in \( L \). Then we have \( \mathbb{Z} \subset O_K \subset A \), with \( O_K \) integral over \( \mathbb{Z} \) and \( A \) integral over \( O_K \). From Theorem 12.13, \( A \) is integral over \( \mathbb{Z} \) and so \( A \subset O_L \). On the other hand, of \( x \in O_L \), then \( x \) is integral over \( \mathbb{Z} \). As \( \mathbb{Z} \subset O_K \), \( x \) is integral over \( O_K \), i.e., \( x \in A \). Thus \( O_L \subset A \). \( \square \)

We now aim to consider in particular integral closures of noetherian domains.

Lemma 12.8 Let \( E \) be a separable extension of \( F \), with \( [E:F] = m \). If \( \{b_1, \ldots, b_m\} \) is a basis of \( E \) over \( F \), then there is a basis \( \{c_1, \ldots, c_m\} \) such that \( T_E/F(b_ic_j) = \delta_{ij} \), where \( \delta_{ij} \) is the Kronecker symbol.

PROOF The trace \( T_{E/F} : E \rightarrow F \) is linear, so \( T_{E/F} \in \text{Hom}(E, F) \), the dual space of the \( F \)-vector space \( E \). We define \( \tau : E \rightarrow \text{Hom}(E, F) \) by

\[
\tau(b)(x) = B(b, x),
\]

where \( B \) is the bilinear form defined by the trace. The mapping \( \tau \) is clearly linear; it is also injective, because \( B \) is nondegenerate. As \( E \) and \( \text{Hom}(E, F) \) have the same dimension, \( \tau \) is an isomorphism. Let \( \{\phi_1, \ldots, \phi_m\} \) be the dual basis of \( \{b_1, \ldots, b_m\} \), so that \( \phi_i(b_j) = \delta_{ij} \). As \( \tau \) is an isomorphism, there exist \( c_1, \ldots, c_m \in E \) such that \( \tau(c_i) = \phi_i \), for \( i = 1, \ldots, m \), therefore

\[
\tau(c_i)(x) = \phi_i(x) \implies \tau(c_i)(b_j) = \delta_{ij} \implies T_{E/F}(c_i b_j) = \delta_{ij},
\]

which is what we set out to prove. \( \square \)

We now consider integral closures of noetherian domains.

Theorem 12.14 Let \( D \) be a noetherian integrally closed domain, with field of fractions \( F \). If \( E \) is a finite separable extension of \( F \) and \( B \) the integral closure of \( D \) in \( E \), then \( B \) is a noetherian ring.

PROOF From Theorem 11.5, \( B \) is a submodule of a finitely generated \( D \)-module, which we note \( M \). As \( D \) is noetherian and \( M \) finitely generated, \( M \) is noetherian. However, a submodule of a noetherian module is noetherian, and so \( B \) is a noetherian \( D \)-module.

Let \( I \) be an ideal in \( B \). Then \( I \) is a submodule of the \( D \)-module \( B \). As \( B \) is a noetherian, \( I \) is finitely generated \( D \)-module: there exist \( x_1, \ldots, x_n \in I \) such that

\[
I = D x_1 + \cdots + D x_n.
\]

Given that \( D \subset B \), we may also write

\[
I = B x_1 + \cdots + B x_n
\]

160
and so $I$ is a finitely generated $B$-module. As every ideal in $B$ is finitely generated, $B$ is noetherian.

Our next step is to show that every prime ideal in the integral closure $B$ as defined above is maximal. We need some preliminary results.

**Lemma 12.9** Let $D$ be a domain which is integral over the subring $R$. If $J$ is a nonzero ideal of $D$, then $J \cap R$ is a nonzero ideal of $R$.

**Proof** $J \cap R$ is clearly an ideal. Let $x \in J$, $x \neq 0$. There exists a monic polynomial $f(X) = a_0 + a_1X + \cdots + a_{n-1}X^{n-1} + X^n \in R[X]$ such that $f(x) = 0$. We may take $f$ of minimal degree, which implies that $a_0 \neq 0$. (If $a_0 = 0$, then $a_1 + a_2x + \cdots + a_{n-1}x^{n-2} + x^{n-1} = 0$, because $x \neq 0$ and $R$ is a domain and so $f$ is not of minimal degree, a contradiction.) Hence

$$a_0 = -(a_1 + a_2x + \cdots + a_{n-1}x^{n-2} + x^{n-1})x \in J \cap R,$$

so $J \cap R \neq \{0\}$.

**Remark** It is easy to see that, if $J$ is a prime ideal, then $J \cap R$ is also a prime ideal.

Before considering the case of maximal ideals we prove another lemma.

**Lemma 12.10** Let $D$ be a domain which is integral over the subring $R$. Then $D$ is a field if and only if $R$ is a field.

**Proof** Suppose that $D$ is a field and let $x$ be a nonzero element of $R$. The inverse $x^{-1}$ of $x$ is integral over $R$, hence there exist $a_1, a_1, \ldots, a_{n-1} \in R$ such that

$$a_0 + a_1x^{-1} + \cdots + a_{n-1}(x^{-1})^{n-1} + (x^{-1})^n = 0.$$

Multiplying by $x^{n-1}$ we obtain

$$a_0x^{n-1} + a_1x^{n-2} + \cdots + a_{n-1}x + x^{-1} = 0,$$

hence $x^{-1} \in R$ and so it follows that $R$ is a field.

Now suppose that $R$ is a field and let $x$ be a nonzero element of $D$. From Lemma 12.9 there exists $a \in Dx \cap R$, $a \neq 0$. We can write $a = bx$, with $b \in D$. Let $a'$ be the inverse of $a$ in $R$. Then

$$1 = a'a = a'(bx) = (a'b)x,$$

and so $x$ is invertible in $D$ and thus $D$ is a field.

**Proposition 12.21** Let $D$ be a domain which is integral over the subring $R$ and $J$ a prime ideal in $D$. Then $J$ is a maximal ideal in $D$ if and only if $J \cap R$ is a maximal ideal in $R$. 
PROOF Let \( J \) be a prime ideal in \( D \). Then the ring homomorphism
\[
\phi : R/(J \cap R) \rightarrow D/J, x + (J \cap R) \mapsto x + J
\]
is injective, so we may consider \( R/(J \cap R) \) to be a subring of \( D/J \). We claim that \( D/J \) is integral over \( R/(J \cap R) \). To see this let us take \( x + J \in D/J \). As \( D \) is integral over \( R \), there exists a monic polynomial
\[
f(X) = a_0 + a_1X + \cdots + a_{n-1}X^{n-1} + X^n \in R[X]
\]
such that \( f(x) = 0 \). To simplify the notation we set \( I = J \cap R \). We define a monic polynomial
\[
f(x) = (a_0 + I) + (a_1 + I)X + \cdots + (a_{n-1} + I)X^{n-1} + X^n.
\]
Then
\[
\bar{f}(x + J) = f(x) + J = J.
\]
As \( J \) is the zero element of \( D/J \), \( x + J \) is integral over \( R/I \). This establishes the claim.

If \( J \) is a maximal ideal in \( D \), then \( D/J \) is a field. From Lemma 12.10 \( R/(J \cap R) \) is a field, therefore \( J \cap R \) is a maximal ideal.

Conversely, if \( J \cap R \) is a maximal ideal in \( R \), then \( R/(J \cap R) \) is a field and so, from Lemma 12.10 again, \( D/J \) is a field and thus \( J \) is a maximal ideal. \( \square \)

We may now establish the principal result of this section.

Theorem 12.15 Let \( D \) be a Dedekind domain, with field of fractions \( F \). If \( E \) is a finite separable extension of \( F \) and \( B \) the integral closure of \( D \) in \( E \), then \( B \) is a Dedekind domain.

PROOF As \( B \) is contained in \( E \), which is a field, \( B \) is an integral domain.

Let \( C \) be the integral closure of \( B \) in its field of fractions. Then \( C \) is integral over \( B \) and \( B \) is integral over \( D \), so \( C \) is integral over \( D \) (Theorem 12.13). Thus, if \( x \in C \), then \( x \in B \) and it follows that \( C = B \), i.e., \( B \) is integrally closed.

To see that \( B \) is noetherian, it is sufficient to apply Theorem 12.14.

Finally, we show that every nonzero prime ideal is maximal. Let \( P \) be a nonzero prime ideal in \( B \). Then \( P = Q \cap D \) is a nonzero prime ideal in \( D \) (Lemma 12.9). As \( D \) is a Dedekind domain, \( P \) is a maximal ideal in \( D \). From Proposition 12.21, \( Q \) is a maximal ideal in \( B \). \( \square \)

Remark From Proposition 11.2 the field of fractions of \( B \) is \( E \). If \( F \neq E \), then \( D \) and \( B \) have different fields of fractions and so are distinct. Thus \( D \) is strictly included in \( B \). We have shown that a Dedekind domain is strictly included in another Dedekind domain.

Let \( C \) be a Dedekind domain and \( D \) an integral domain containing \( C \). If \( P \) is a nonzero prime ideal in \( C \), then \( C/P \) is a field and the mapping
\[
\phi : C/P \rightarrow D/DP, a + P \mapsto a + DP
\]
is a well-defined homomorphism. Hence we may consider that \( D/DP \) is a \( C/P \)-vector space.

(The scalar multiplication is defined as follows: \( \overline{c} \overline{x} = \phi(\overline{c})\overline{x} \), for \( \overline{c} \in C/P \) and \( \overline{x} \in D/DP \).) There is a natural question: If \( K \) and \( L \) are the respective fraction fields of \( C \) and \( D \) and we know the dimension \( [K : L] \), what can we say about the dimension of the \( C/P \)-vector space \( D/DP \)? We aim to give an answer to this question for a particular integral domain \( D \). We will need the following standard result, for which a proof may be found, for example, in [5].
Theorem 12.16 If $R$ is a PID and $M$ a free $R$-module of rank $n$, then any submodule $N$ of $M$ is free and has rank at most $n$.

Theorem 12.17 Let $C$ be a Dedekind domain, $K$ its field of fractions and $L$ a separable extension of $K$ of degree $n$. Suppose that $D$ is the integral closure of $C$ in $L$. If $P$ is a nonzero prime ideal in a Dedekind domain, hence maximal. We now consider $D/P$, to $D'$ is a submodule of $M$, from Theorem 12.16, $D'$ is a free $C'$-module of rank at most $n$. Using Theorem 11.5 again, we obtain that $D'$ contains a free $C'$-module of rank $n$. Thus, using Theorem 12.16 again, we obtain that $D'$ is a free $C'$-module of rank $n$.

We now consider the mappings

$$
\psi : C'/C'P \rightarrow D'/D'P, \bar{c}' \rightarrow \bar{c} + D'P
$$

is a ring homomorphism. Since $C'/C'P$ is the maximal ideal of the local ring $C'$, the quotient $C'/C'P$ is a field. Thus $D'/D'P$ is a $C'/C'P$-vector space. (The scalar multiplication is defined by $\bar{c}' \cdot \bar{x}' = \psi(\bar{c}') \bar{x}'$, for $\bar{c}' \in C'/C'P$ and $\bar{x}' \in D'/D'P$.) We now consider the dimension of this vector space.

We have seen that $D'$ is a free $C'$-module of rank $n$, so $D'$ has a basis $B' = \{x'_1, \ldots, x'_n\}$. Let us write $x'_i$ for the image of $x'_i$ in $D'/D'P$ (under the standard mapping of $D'$ onto $D'/D'P$). We claim that $B' = \{x'_1, \ldots, x'_n\}$ is a basis of $D'/D'P$. Clearly $B'$ is a generating set of $D'/D'P$, so we only need to consider the independence. Let $\sum_{i=1}^n c'_i x'_i = 0$, where $c'_i \in C'/C'P$. Then

$$
\sum_{i=1}^n c'_i x'_i \in D'P = D'(C'P)
$$

and so we may write $\sum_{i=1}^m c'_i x_i = \sum_{j=1}^m c'_j y'_j$, with $y'_j \in D'$ and $c'_j \in C'P$. Expressing the $y'_j$ in terms of the $x'_i$, we obtain $\sum_{i=1}^n c'_i x_i = \sum_{i=1}^n c'_i x'_i$, with $c'_i \in C'P \subset C'$. It follows that $c'_i = 0$, for all $i$. We have shown that $B'$ is an independent set and so a basis of $D'/D'P$: $D'/D'P$ is a $C'/C'P$-vector space of dimension $n$.

We now consider the mappings

$$
\alpha : C/P \rightarrow C'/C'P, \bar{c} + P \mapsto \bar{c} + C'P \quad \text{and} \quad \beta : D/P \rightarrow D'/D'P, d + P \mapsto d + D'P.
$$

These mappings $\alpha$ and $\beta$ are clearly well-defined ring homomorphisms. We aim to use Corollary 12.11 to show that they are in fact isomorphisms. For $\alpha$ there is no difficulty, because $P$ is a prime ideal in a Dedekind domain, hence maximal. We now consider $\beta$. Let us set $U = C \setminus P$. Because $C/P$ is a field, for $u \in U$ there exists $v \in U$ and $x \in P$ such that $uv = 1 + x$. As $P \subset DP$, every element of $U + DP$ has an inverse in the same set and it follows that $\beta$ is an isomorphism.

We now notice that $D'/D'P$ is a $C/P$-vector space for the scalar multiplication $\bar{c} \cdot \bar{x}' = \alpha(\bar{c}) \bar{x}'$, where $\bar{c} \in C/P$ and $\bar{x}' \in D'/D'P$. (We distinguish scalar multiplication and ring multiplication by using a dot in the former case.) It is not difficult to check that $B'$ is a basis of this vector space, so it too has dimension $n$. We claim that $\beta$ is an isomorphism of $C/P$-vector spaces. We
only need to verify that the scalar multiplication is respected. Let \( \bar{c} \in C/P \) and \( \bar{x} \in D/DP \). Then

\[
\beta(\bar{c} \cdot \bar{x}) = \beta(\phi(\bar{c}) \bar{x}) = \beta(\tilde{\phi}(\bar{c})) \beta(\bar{x}),
\]

with \( \beta(\phi(\bar{c})) = \tilde{c} + D'P \). Thus

\[
\beta(\tilde{\phi}(\bar{c})) \beta(\bar{x}) = (\tilde{c} + C'P) \cdot \beta(\bar{x}) = \alpha(c + P) \cdot \beta(\bar{x}) = \tilde{c} \cdot \beta(\bar{x})
\]

and so

\[
\beta(\bar{c} \cdot \bar{x}) = \tilde{c} \cdot \beta(\bar{x}),
\]

as required. Since \( D'/D'P \) is a \( C/P \)-vector space of dimension \( n \), so is \( D/DP \). This finishes the proof. \( \square \)

### 12.8 Norm and trace for ring extensions

We have studied traces and norms in field extensions. We now consider ring extensions. We suppose that \( R \subset S \) are commutative rings. In addition we consider that \( S \) is a free \( R \)-module whose rank \( n \) is finite. Let \( B = \{ x_1, \ldots, x_n \} \) be a basis of the \( R \)-module \( S \) and \( \theta : S \rightarrow S \) a linear mapping. We have

\[
\theta(x_j) = \sum_{i=1}^{n} a_{ij} x_i,
\]

with \( a_{ij} \in R \). The matrix \( M(\theta) = (a_{ij}) \) is called the matrix of \( \theta \) with respect to the basis \( B \). If \( B' = \{ x'_1, \ldots, x'_n \} \) is another basis of the \( R \)-module \( S \), then

\[
\theta(x'_j) = \sum_{i=1}^{n} a'_{ij} x'_i,
\]

with \( a'_{ij} \in R \). We note the matrix with respect to this basis \( M'(\theta) \). We now look for the relation between the matrices \( M(\theta) \) and \( M'(\theta) \). If \( x_j = \sum_{i=1}^{n} c_{ij} x'_i \), then

\[
\theta(x_j) = \sum_{i=1}^{n} a_{ij} x_i = \sum_{i=1}^{n} a_{ij} \left( \sum_{k=1}^{n} c_{ki} x'_k \right) = \sum_{k=1}^{n} \left( \sum_{i=1}^{n} c_{ki} a_{ij} \right) x'_k
\]

and, on the other hand

\[
\theta(x_j) = \sum_{i=1}^{n} c_{ij} \theta(x'_i) = \sum_{i=1}^{n} c_{ij} \left( \sum_{k=1}^{n} a'_{ki} x'_k \right) = \sum_{k=1}^{n} \left( \sum_{i=1}^{n} a'_{ki} c_{ij} \right) x'_k.
\]

Therefore, with \( C = (c_{ij}) \), we have

\[
M'(\theta)C = CM(\theta).
\]

As \( C \) is the matrix of a change of basis, \( C \in \text{Gl}_n(R) \), hence we may write

\[
M'(\theta) = CM(\theta)C^{-1}.
\]

(12.4)

Also, as

\[
\det(C) \det(C^{-1}) = \det(I_n) = 1,
\]

164
We now consider the special case where \( \theta \) is defined by multiplication by a nonzero element of \( S \):

\[
\theta(z) = \theta_x(z) = xz.
\]

We define the trace, norm and characteristic polynomial of \( x \) as we did for field extensions, namely

\[
T_{S/R}(x) = \text{Tr}(M(\theta_x)) \quad N_{S/R}(x) = \det M(\theta_x)
\]

and

\[
\text{char } S/R(x) = \det (XI - M(\theta_x)).
\]

(The relation (12.4) ensures that the trace, norm and characteristic polynomial are unaffected by the choice of basis.) In the same way as for field extensions, the trace is linear and the norm multiplicative.

We now turn to rings of fractions. Let \( U \) be a multiplicative subset of \( R \). As \( R \subset S \), \( U \) is also a multiplicative subset of \( S \). We set \( R' = U^{-1}R \) and \( S' = U^{-1}S \). It is not difficult to see that \( R' \subset S' \), so \( S' \) is an \( R' \)-module. Let \( B = \{x_1, \ldots, x_n\} \) be a basis of the \( R \)-module \( S \). We claim that \( B' = \{\frac{x_1}{u_1}, \ldots, \frac{x_n}{u_n}\} \) is a basis of the \( R' \)-module \( S' \), hence \( S' \) is a free \( R' \)-module of rank \( n \).

First we show that \( B' \) is a generating set of \( S' \). Let \( \frac{x_i}{u_i} \in S' \). Then there exist \( r_1, \ldots, r_n \in R \) such that

\[
\frac{a}{u} = \frac{r_1 x_1 + \cdots + r_n x_n}{u} = \frac{r_1}{u} \frac{x_1}{1} + \cdots + \frac{r_n}{u} \frac{x_n}{1},
\]

which implies that \( B' \) is a generating set of \( S' \). Now we show that the set \( B' \) is independant. If \( \frac{r_1}{u_1} \frac{x_1}{1} + \cdots + \frac{r_n}{u_n} \frac{x_n}{1} = 0 \), with \( \frac{r_i}{u_i} \in R' \), then

\[
r_1 u'_i x_1 + \cdots + r_n u'_n x_n = 0,
\]

where \( u'_i = \frac{u_1 \cdots u_n}{u_i} \). Hence

\[
r_1 u'_1 = \cdots = r_n u'_n = 0 \implies r_1 = \cdots = r_n = 0,
\]

because \( u'_i = 0 \), for all \( i \). It follows that \( \frac{r_i}{u_i} = 0 \), for all \( i \) and so \( B' \) is an independant set. We have shown that \( B' \) is a basis of the \( R' \)-module \( S' \).

Let \( \gamma \) be the canonical mapping from \( S \) into \( S' \). If \( x \in S \), then \( \gamma(x) \in S' \) and we have linear endomorphisms \( \theta_x : S \to S \) and \( \theta'_x : S' \to S' \). If the matrix of \( \theta_x \) in the basis \( B \) is \((a_{ij})\), then the matrix of \( \theta'_x(\gamma(x)) \) in the basis \( B' \) is \((\gamma(a_{ij}))\).

\[
T_{S'/R'}(\gamma(x)) = \gamma(T_{S/R}(x)) \quad N_{S'/R'}(\gamma(x)) = \gamma(N_{S/R}(x))
\]

and

\[
\text{char } S'/R'(\gamma(x)) = \gamma^*(\text{char } S/R(x)),
\]

where \( \gamma^* \) is the mapping from \( R[X] \) into \( R'[X] \) which applies \( \gamma \) to each coefficient of a polynomial in \( R[X] \). Identifying \( S \) with its image under \( \gamma \), we obtain

\[
T_{S'/R'}(x) = T_{S/R}(x) \quad N_{S'/R'}(x) = N_{S/R}(x)
\]

and

\[
\text{char } S'/R'(x) = \text{char } S/R(x).
\]

165
Chapter 13

Ramification theory

Let $K$ and $L$ be number fields, with $K$ included in $L$, and $R = O_K$ and $S = O_L$ the associated number rings. If $I$ is an ideal in $R$, then we write $SI$ for the ideal generated by $I$ in $S$: $SI$ is the collection of expressions of the form $\sum_{i=1}^{n} x_i y_i$, with $x_i \in S$ and $y_i \in I$. If $I$ is a principal ideal $(a)$, then $SI = Sa$, i.e., the prime ideal generated by $a$ in $S$. We will be particularly interested in the case where $I$ is a prime ideal and the relation of such an ideal with prime ideals in $S$.

For example, $I = \mathbb{Z}2$ is a prime ideal in $\mathbb{Z}$, but $J = \mathbb{Z}[\sqrt{2}]2$ is not a prime ideal in $\mathbb{Z}[\sqrt{2}]$, since $(2 + 3\sqrt{2})^2 \in J$, but $2 + 3\sqrt{2} \notin J$. The way a prime ideal "lifted" to a larger ring is decomposed is a central topic of algebraic number theory.

Remark The ideal $SI$ is in fact the extension of the ideal $I$ in $S$ with respect to the injection mapping of $R$ into $S$.

13.1 First notions

Let $P$ be a prime ideal in $R$; if $Q$ is a prime ideal in $S$ such that $Q \supset SP$, then we say that $Q$ lies over $P$, or $P$ lies under $Q$.

Remark If $K = \mathbb{Q}$, then $R = \mathbb{Z}$ and a prime ideal $P \neq \{0\}$ is of the form $(p) = \mathbb{Z}p$, where $p$ is a prime number, so $SP = Sp$.

Proposition 13.1 Let $Q$ be a proper ideal of $S$ and $P$ a nonzero prime ideal of $R$. Then $Q \supset SP$ if and only if $P = Q \cap R$.

PROOF If $Q \supset SP$, then $Q \supset P$, because $1 \in S$. This implies that $Q \cap R \supset P \cap R = P$. As $P$ is a maximal ideal, because $P$ is prime and nonzero, and $Q \cap R \neq R$, we have $Q \cap R = P$.

On the other hand, if $Q \cap R = P$, then $Q \supset P$, which implies that $Q = SQ \supset SP$. \hfill \Box

Proposition 13.2 If $I$ is a proper ideal in $R$, then $SI$ is a proper ideal in $S$.

PROOF If $SI = S$, then there exist $n \in \mathbb{N}^*$, $s_1, \ldots, s_n \in S$ and $x_1, \ldots, x_n \in I$ such that

$$1 = \sum_{i=1}^{n} s_i x_i.$$ 

Let $S' = R[s_1, \ldots, s_n]$ be the subring of $S$ generated by $R$ and the elements $s_1, \ldots, s_n$. The ring $S'$ is a finitely generated $R$-module, since the $s_i$ are algebraic integers. In addition, as $1 \in S'I$,
We now take a set of generators \( g_1, \ldots, g_n \) of the \( R \)-module \( S' \). Because \( S' \subset S'I \), we may write
\[
g_i = \sum_{j=1}^{k_i} x_{ij} s_{ij} = \sum_{j=1}^{k_i} x_{ij} \left( \sum_{u=1}^{n} r_{uj}^{ij} g_u \right) = \sum_{u=1}^{n} \left( \sum_{j=1}^{k_i} x_{ij} r_{uj}^{ij} \right) g_u,
\]
where \( x_{ij} \in I \), \( s_{ij} \in S' \) and \( r_{uj}^{ij} \in R \). As \( \sum_{j=1}^{k_i} x_{ij} r_{uj}^{ij} \in I \), we have
\[
g_i = \sum_{u=1}^{n} x_u g_u,
\]
with \( x_u \in I \). Hence there is a matrix \( A \in M_n(I) \) such that
\[
g = Ag,
\]
where
\[
g = \begin{pmatrix} g_1 \\ \vdots \\ g_n \end{pmatrix}.
\]
Therefore, \((I_n - A)g = 0\). Multiplying on the left by the adjoint matrix of \( I_n - A \), we obtain \( \det(I_n - A)I_n g = 0 \). Consequently \( \det(I_n - A)s' = 0 \), for any \( s' \in S' \), which implies that \( \det(I_n - A) = 0 \). If we develop the determinant, then we obtain an expression which is 1 plus a sum of products of elements of \( I \), i.e., of the form \( 1 + x \), with \( x \in I \). From this we have \( 1 = -x \in I \), which contradicts the fact that \( I \) is a proper ideal of \( R \). We have shown that \( S'I \) is properly contained in \( S \).

**Exercise 13.1** In the proof of the theorem we used the fact that the \( s_i \) are algebraic integers. Why is this important?

**Corollary 13.1** Let \( P \) be prime ideal in \( R \). Then \( SP \cap R = P \).

**Proof** If \( P = \{0\} \), then the result is clear, so let us suppose that this is not the case. As \( P \) is a prime ideal of \( R \), \( P \) is a proper ideal of \( R \), therefore \( SP \) is a proper ideal of \( S \). From Proposition 13.1, with \( Q = SP \), we have \( SP \cap R = P \).

**Remarks**

- **a.** Corollary 13.1 is in fact a particular case of Theorem 12.7.
- **b.** If \( K = Q \) and \( P = \mathbb{Z}p \), where \( p \) is prime number, then we obtain
\[
O_{LP} \cap \mathbb{Z} = \mathbb{Z}p.
\]

It is natural to ask whether there exists a prime ideal lying over a given prime ideal.

**Theorem 13.1** Every nonzero prime ideal \( Q \) of \( S \) lies over a unique nonzero prime ideal \( P \) of \( R \).
Every prime ideal \( P \) of \( R \) lies under at least one prime ideal \( Q \) of \( S \). If \( P \neq \{0\} \), then there is a finite number of prime ideals \( Q \) lying over \( P \).
PROOF Let $Q$ be a nonzero prime ideal of $S$. Clearly $P = Q \cap R$ is a prime ideal of $R$. Since $Q \neq \{0\}$, there is a nonzero integer $x \in Q$ (Proposition 11.13). As $x \in R$, $x \in Q \cap R$, so $P \neq \{0\}$. If $Q$ lies over the nonzero prime ideal $P'$, then, from Proposition 13.1, $P' = Q \cap R$, so $Q$ lies over a unique prime ideal.

Suppose now that $P$ is a prime ideal of $R$. If $P = \{0\}$, then $P$ lies under $\{0\} \subset S$. Now let us suppose that $P \neq \{0\}$. We claim that a prime ideal $Q$ of $S$ contains $SP$ if and only if $Q$ appears in the decomposition of $SP$ into prime ideals: From Corollary 12.2, $Q \supset SP$ if and only if $Q|SP$, as $SP \neq \{0\}$ nor $S$, from Theorem 12.3, $SP$ has a unique decomposition into nonzero prime ideals. So $Q$ divides $SP$ if and only if it is one of the prime ideals in the decomposition of $SP$. It follows that $P$ lies under a prime ideal of $S$, namely any prime ideal in the decomposition of $SP$. These are the only ideals which can lie over $P$, so the number of prime ideals lying over $P$ is finite.

Exercise 13.2 Use Theorem 13.1 to find a proof that a prime ideal $P$ in a number ring $O_K$ contains exactly one prime number $p$. (This result has already been seen in Proposition 13.6.)

If $P$ is a nonzero prime ideal of $R$, $Q$ a nonzero prime ideal of $S$ dividing $SP$ and $e$ the highest power of $Q$ in the decomposition of $SP$ into prime ideals, then we call $e$ the ramification index of $Q$ over $P$. We note the ramification index $e(Q|P)$. In the case where $R = \mathbb{Z}$ and $P = \mathbb{Z}p$, then we write $e(Q|p)$.

Suppose again that $P$ is a nonzero prime ideal of $R$ and $Q$ a nonzero prime ideal of $S$ dividing $SP$. As $P$ and $Q$ are maximal ideals, $R/P$ and $S/Q$ are fields, which, from Proposition 11.12, are finite. The mapping

$$
\phi : R \rightarrow S/Q, x \mapsto x + Q
$$

is a well-defined ring homomorphism, with kernel $Q \cap R = P$, so we may consider $R/P$ as a subfield of $S/Q$. We set $f(Q|P) = [S/Q : R/P]$, which is called the inertial degree of $Q$ over $P$. In the case where $R = \mathbb{Z}$ and $P = \mathbb{Z}p$, we write $f(Q|p)$.

We often say that the ramification index and the inertial degree are multiplicative due to the properties given in the following proposition.

Proposition 13.3 Suppose that $P$, $Q$ and $U$ are nonzero prime ideals in the number rings $R \subset S \subset T$ such that $U$ lies over $Q$ and $Q$ lies over $P$. Then $U$ lies over $P$ and

$$
e(U|P) = e(U|Q)e(Q|P) \quad \text{and} \quad f(U|P) = f(U|Q)f(Q|P).$$

PROOF $Q$ lies over $P$ means that we have

$$SP = Q^{e(Q|P)}Q_2^{e_2} \cdots Q_s^{e_s},$$

where $e_i = e(Q_i|P)$. Since $TS = T$ and $T^n = T$, for all $n \in \mathbb{N}^*$, when we multiply the previous expression by $T$ we obtain

$$TP = (TQ)^{e(Q|P)}(TQ_2)^{e_2}\cdots(TQ_s)^{e_s}.$$

Now, $U$ lies over $Q$, so we can write

$$TQ = U^{e(U|Q)}U_2^{e_2}\cdots U_t^{e_t},$$

where $a_i = e(U_i|Q)$. Hence,

$$TP = U^{e(U|Q)e(Q|P)}U_2^{e_2e(Q|P)}\cdots U_t^{e_te(Q|P)}(TQ_2)^{e_2}\cdots(TQ_s)^{e_s}.$$
Moreover, $U$ does not divide $TQ_i$, for $i = 2, \ldots, s$. Indeed, if $U|TQ_i$, then $U|TQ$ and $U|TQ_i$, which implies that $U \supset T(Q + Q_i) = \text{Thcf}(Q, Q_i) = TS = T$,

which is not possible. Therefore $U$ lies over $P$ and $e(U|P) = e(U|Q)e(Q|P)$.

We now consider the inertial degree. $S/Q$ is a field extension of $R/P$ and $T/U$ is a field extension of $S/Q$, so we have

$$f(U/P) = [T/U : R/P] = [T/U : S/Q][S/Q : R/P] = f(U|Q)f(Q|P),$$

as claimed.

### 13.2 Norm of an ideal

In this section we introduce the norm of an ideal in a number ring, which will play an important role in the following. We have seen above that $|O_K/I|$ is finite when $I$ is a nonzero ideal (Proposition 11.12). We define the norm of $I$ by $\|I\| = |O_K/I|$. The norm has an important multiplication property, namely, if $I$ and $J$ are nonzero ideals, then $\|IJ\| = \|I\|\|J\|$.

We will first prove this in the case where the ideals are coprime and then later in the general case.

**Proposition 13.4** If $I$ and $J$ are nonzero coprime ideals in a number ring $O_K$, then $\|IJ\| = \|I\|\|J\|$.

**Proof** From the Chinese remainder theorem (Appendix F) we have

$$O_K/(I \cap J) = O_K/I \times O_K/J.$$ 

However, from Proposition 12.4, $I \cap J = IJ$, hence the result. $\square$

We now generalize Proposition 13.4.

**Theorem 13.2** If $I$ and $Q$ are nonzero ideals in a number ring $O_K$, then $\|IQ\| = \|I\||Q|$.

**Proof** From Theorem 12.5, there is an ideal $J$ in $O_K$, coprime with $Q$, such that $IJ$ is principal. Let $IJ = (x)$. Then

$$(x) + IQ = I(J + Q) = I(O_K) = I.$$

(13.1)

We now define a mapping $\phi$ from $O_K$ into $I/IQ$ by

$$\phi(a) = ax + IQ.$$ 

169
The mapping $\phi$ is an $O_K$-module homomorphism, which, from equation 13.1, is surjective. Also,

$$\text{Ker} \phi = \{a \in O_K : ax \in IQ\}.$$ 

We claim that $\text{Ker} \phi = Q$. First,

$$ax \in IQ \iff (a)(x) \subset IQ \iff (a)I J \subset IQ \iff (a)J \subset Q,$$

thus, for all $a \in \text{Ker} \phi$,

$$(a) = (a)O_K = (a)(J + Q) = (a)J + (a)Q \subset Q + Q = Q.$$ 

This implies that $\text{Ker} \phi \subset Q$. In addition, if $a \in Q$, then $ax \in IQ$, since $x \in I$, and so $Q \subset \text{Ker} \phi$ and we have $\text{Ker} \phi = Q$.

As $\phi$ is surjective, from the third isomorphism theorem for groups, we have

$$O_K/Q \simeq I/IQ \implies \|Q\| = |I/IQ|.$$ 

This ends the proof.

If $K$ is a number field, with $[K : \mathbb{Q}] = n$ and $I$ a nonzero ideal in $O_K$, then $I$ is a free abelian group of rank $n$ (Corollary 11.5). From a basis of $I$ we may obtain an expression for the norm of $I$.

**Theorem 13.3** If $B = \{b_1, \ldots, b_n\}$ is a basis of $I$, then

$$\|I\| = \left| \frac{\text{disc}_{K/Q}(B)}{\text{disc}(O_K)} \right|^\frac{1}{2}.$$ 

**Proof** From Theorem E.4, there exists a basis $E = \{e_1, \ldots, e_n\}$ of $O_K$ and numbers $d_1, \ldots, d_n \in \mathbb{N}^*$ such that $D = \{d_1 e_1, \ldots, d_n e_n\}$ is a basis of $I$. We define a mapping $\phi$ of $O_K$ onto $\mathbb{Z}_{d_1} \times \cdots \times \mathbb{Z}_{d_n}$ in the following way:

if $x = x_1 e_1 + \cdots + x_n e_n$, then $\phi(x) = (x_1 + d_1 \mathbb{Z}, \ldots, x_n + d_n \mathbb{Z})$.

The mapping $\phi$ is a ring homomorphism and $\text{Ker} \phi = I$, hence

$$O_K/I \simeq \mathbb{Z}_{d_1} \times \cdots \times \mathbb{Z}_{d_n} \implies |O_K/I| = d_1 \cdots d_n.$$ 

If we set $C = \text{diag}(d_1, \ldots, d_n)$, then $C$ is the matrix transforming the basis $E$ into the basis $D$ and

$$|O_K/I| = \det C.$$ 

If $B = \{b_1, \ldots, b_1\}$ is any basis of $I$, then the $b_i$ are linear combinations of the elements of $D$ with integer coefficients. The matrix $M$ transforming the basis $B$ into the basis $D$ thus has integer coefficients. This is also the case of the matrix $N$ transforming the basis $D$ into the basis $B$. It follows that $\det M = \pm 1$ (and also that $\det N = \pm 1$). It follows that the matrix $C^\ast$
expressing the basis $\mathcal{B}$ in terms of the elements of the basis $\mathcal{E}$ is such that $\det C' = \pm \det C$ and so

$$|O_K/I| = |\det C'| = d_1 \cdots d_n.$$  

However, from Proposition 10.6,

$$\text{disc}_{K/Q}(\mathcal{B}) = |\det C'|^2 \text{disc}_{K/Q}(\mathcal{E}) = \|I\|^2 \text{disc}(O_K),$$

from which we deduce

$$\|I\| = \left|\frac{\text{disc}_{K/Q}(\mathcal{B})}{\text{disc}(O_K)}\right|^{\frac{1}{2}}.$$  

This finishes the proof. \hfill \Box  

If an ideal $I$ of $O_K$ is principal and $I = (a)$, then we consider two norms, namely the norm of the generator $a$ and the norm of the ideal. In fact, we have

**Theorem 13.4** If $a \in O_K \setminus \{0\}$, then

$$|N_{K/Q}(a)| = \|(a)\|.$$  

**Proof** Let $\mathcal{E} = \{e_1, \ldots, e_n\}$ be a basis of $O_K$. Then $\mathcal{B} = \{ae_1, \ldots, ae_n\}$ is a basis of $(a)$. Now

$$\text{disc}_{K/Q}(\mathcal{B}) = (\det(\sigma_i(\sigma_j)))^2 = (\det(\sigma_i(\sigma_j)))^2 = (\sigma_1(a) \cdots \sigma_n(a) \det(\sigma_i(e_j)))^2 = (\sigma_1(a) \cdots \sigma_n(a))^2 \text{disc}(O_K).$$

By Theorem 13.3, we have

$$\|I\| = \left|\frac{\text{disc}_{K/Q}(\mathcal{B})}{\text{disc}(O_K)}\right|^{\frac{1}{2}} = \|a\| = |N_{K/Q}(a)|,$$

as required. \hfill \Box  

We will now investigate further the properties of the norm.

**Proposition 13.5** Let $K$ be a number field, $O_K$ its associated number ring and $I$ a nonzero ideal in $O_K$.

- **a.** If $\|I\|$ is prime, then $I$ is a prime ideal.
- **b.** $\|I\| \in I$.

**Proof**

- **a.** If $I = P_1 \cdots P_s$, where the $P_i$ are prime ideals, then

$$\|I\| = \|P_1\| \cdots \|P_s\|.$$  

As $\|I\|$ is prime, only one $P_i$, say $P_1$, has a norm different from 1. This means that $P_2 = \cdots = P_s = O_K$ and so $I = P_1$.  

171
Lemma 13.1 A nonzero integer belongs to at most a finite number of ideals in $O_K$.

Proof Let $a$ be a positive integer and suppose that $I$ is an ideal containing $a$. We now let $B = \{w_1, \ldots, w_n\}$ be an integral basis of $O_K$. If $a \in O_K$, then there exist $c_1, \ldots, c_n \in \mathbb{Z}$ such that
\[
\alpha = c_1 w_1 + \cdots + c_n w_n.
\]
For each $c_i$ we may write $c_i = a q_i + r_i$, where $q_i, r_i \in \mathbb{Z}$ and $0 \leq r_i < a$. Then
\[
\alpha = (aq_1 + r_1) w_1 + \cdots + (aq_n + r_n) w_n = a(q_1 w_1 + \cdots + q_n w_n) + r_1 w_1 + \cdots + r_n w_n = a \gamma + \beta.
\]
Clearly $\gamma \in O_K$ and $\beta \in B$, where $B$ is a finite subset of $O_K$. The ideal $I$ is finitely generated, because $O_K$ is noetherian, so there exist $\alpha_1, \ldots, \alpha_s \in O_K$, such that
\[
I = (\alpha_1, \ldots, \alpha_s).
\]
As $a \in I$, we may also write
\[
I = (\alpha_1, \ldots, \alpha_s, a)
\]
and then
\[
I = (a \gamma_1 + \beta_1, \ldots, a \gamma_s + \beta_s, a),
\]
where $\gamma_1, \ldots, \gamma_s \in O_K$ and $\beta_1, \ldots, \beta_s \in B$. It is not difficult to derive the expression
\[
I = (\beta_1, \ldots, \beta_s, a).
\]
As there is a finite number of ideals of this form, the result follows for the case $a > 0$.

If $a < 0$ and $a$ belongs to an infinite number of ideals, then so does $-a$, which contradicts what we have just proved. This finishes the proof.

We may now prove an interesting result concerning the number of ideals having a given norm.

Theorem 13.5 There is only a finite number of ideals in $O_K$ of a given norm.

Proof Suppose that there is an infinite number of ideals having the same norm $\alpha$. From Proposition 13.5, $\alpha$ belongs to an infinite number of ideals, which contradicts Lemma 13.1. Therefore there can be only a finite number of ideals with a given norm.

We now consider the special case where $I$ is a prime ideal.

Proposition 13.6 If $P$ is a nonzero prime ideal in $O_K$, then $P$ contains exactly one prime number $p$ and $\|P\| = p^m$, for some natural number $m \leq n = [K : \mathbb{Q}]$. 

172
Proof If \( P \) is a prime ideal, then \( P \) is maximal and so \( \mathcal{O}_K/P \) is a finite field. It follows that \( \|P\| = p^m \), for some prime number \( p \) and positive integer \( m \). The characteristic of the field \( \mathcal{O}_K/P \) is \( p \), which implies that the number \( p \in P \) and so the principal ideal \( (p) = \mathcal{O}_Kp \) is contained in \( P \). If \( q \neq p \) and \( q \in P \), then \( (q) = \mathcal{O}_Kq \) is also contained in \( P \). However, \( (p) + (q) = \mathcal{O}_K \), so \( \mathcal{O}_K \subset P \), which is impossible; hence there is a unique prime number \( p \) in \( P \).

As \( (p) \) is a subset of \( P \), \( P \) divides \( (p) \), hence \( \|P\| \) divides \( ||(p)|| \). From Theorem 13.4, \( ||(p)|| = N_{\mathcal{O}_K/Q}(p) = p^n \), therefore \( \|P\| = p^m \), with \( m \leq n \).

13.3 Principal theorem of ramification

Our goal in this section is to prove an important result connecting ramification indices and inertial degrees. We will refer to this as the principal theorem of ramification. We begin with a special case of this result and then generalize it.

**Proposition 13.7** Let \( p \) be a prime number and \( L \) an extension of \( K = \mathbb{Q} \), with number field \( S \).

If \( n = [L : \mathbb{Q}] \) and \( S_p = \mathcal{O}_1^{e_1(p)} \cdots \mathcal{O}_s^{e_s(p)} \) is the decomposition of \( S_p \) into nonzero prime ideals, then

\[ n = \sum_{i=1}^{s} f(Q_i|p)e(Q_i|p). \]

Proof To simplify the notation, let us write \( e_i \) for \( e(Q_i|p) \) and \( f_i \) for \( f(Q_i|p) \). From Theorem 13.2 we have

\[ \|S_p\| = \|Q_1\|^{e_1} \cdots \|Q_s\|^{e_s}. \]

Also,

\[ f_i = [S/\mathcal{O}_i : \mathbb{Z}/p\mathbb{Z}] \implies \|Q_i\| = p^{f_i}, \]

therefore

\[ \|S_p\| = p^{f_1e_1} \cdots p^{f_se_s}. \]

However, from Theorem 13.4 and Section 10.1

\[ \|S_p\| = |N_{L/\mathbb{Q}}(p)| = p^n, \]

so we have

\[ n = \sum_{i=1}^{s} f(Q_i|p)e(Q_i|p), \]

as announced. \( \square \)

We aim now to generalize this proposition to the case where \( K \) is not necessarily \( \mathbb{Q} \). We will begin with a preliminary result.

**Lemma 13.2** Let \( I, J \) be nonzero ideals in a Dedekind domain \( D \), with \( J \subset I \neq D \), and \( K \) the field of fractions of \( D \). Then there exists \( \gamma \in K \) such that \( \gamma J \subset D \) and \( \gamma J \nsubset I \).
Proof From Theorem 12.2 we know that there is a nonzero ideal $C$ in $D$ such that $JC$ is principal: $JC = (a)$. Then $JC \not\subset aI$, because

$$JC \subset aI \implies \frac{1}{a}JC \subset I \implies 1 \in I \implies I = D,$$

a contradiction. We now take $b \in C$ such that $bJ \not\subset aI$ and set $\gamma = \frac{b}{a}$. Then

$$\gamma J = \frac{b}{a}J \subset \frac{1}{a}JC = \frac{1}{a}(a) = D.$$

If $\gamma J \subset I$, then $bJ \subset aI$, a contradiction, so $\gamma J \not\subset I$. \hfill \Box

We now establish another preliminary result. This is a little longer to prove.

**Proposition 13.8** Let $K \subset L$ be number fields, with corresponding number rings $R \subset S$, and $I$ a nonzero ideal in $R$. Then

$$\|SI\| = \|I\|^n,$$

where $n = [L : K]$.

Proof It is sufficient to prove the result for a prime ideal: If this is the case and $I = P_1 \cdots P_r$ is the decomposition of the ideal $I$ into prime ideals, then

$$\|SI\| = \|P_1 \cdots P_r S\| = \|P_1 S \cdots P_r S\| = \|P_1 S\| \cdots \|P_r S\| = \|P_1\|^n \cdots \|P_r\|^n = \|I\|^n.$$

So let us now establish the result for a nonzero prime ideal $P$.

To begin with, we notice that $S/SP$ is a vector space over the field $R/P$. (The scalar multiplication is defined by

$$(x + P)(y + PS) = xy + SP.$$  

There is no difficulty in seeing that this scalar multiplication is well-defined.) We claim that the dimension of the vector space we have defined is $n$. First we show that the dimension is at most $n$. Let $a_1, \ldots, a_{n+1} \in S$ and consider the corresponding cosets of $S/SP$. The $a_i$ are linearly dependant over $K$, because they are elements of $L$ and $n = [L : K]$. As $K$ is the field of fractions of $R$, the $a_i$ are linearly dependant over $R$. Hence we have

$$\beta_1 a_1 + \cdots + \beta_{n+1} a_{n+1} = 0,$$

with $\beta_i \in R$ and at least one $\beta_i$ nonzero. We need to show that we can find $\beta'_1, \ldots, \beta'_{n+1} \in R$ such that

$$\beta'_1 a_1 + \cdots + \beta'_{n+1} a_{n+1} = 0,$$

and at least one $\beta'_i \not\in P$. If one of the $\beta_i \not\in P$, then we have nothing to do, so let us suppose that all the $\beta_i$ belong to $P$. If $J$ is the ideal generated by the $\beta_i$, then $J \subset P \neq R$. Applying Lemma 13.2 we obtain an element $\gamma \in K$ such that $\gamma J \subset R$ and $\gamma J \not\subset P$. If we replace $\beta_i$ by $\beta'_i = \gamma \beta_i$, then the set of $\beta'_i$ so obtained has the properties we were looking for. Thus we have shown that $S/SP$ is at most $n$-dimensional over $R/P$.  

174
Now we establish the equality. As $P \cap \mathbf{Z}$ is a nonzero ideal of $\mathbf{Z}$, there is a prime number $p \in \mathbf{Z}$ such that $P \cap \mathbf{Z} = p \mathbf{Z}$. We consider the prime ideals $P_1, \ldots, P_r$ of $R$ lying over $p \mathbf{Z}$. From Proposition 13.1 $P$ is one of the ideals $P_i$. From what we have just seen $S/S_{P_i}$ is a vector space over $R/P_i$ of dimension $n_i \leq n$. Also, from Proposition 13.7 we have

$$m = \sum_{i=1}^{r} f(P_i)p e(P_i)p = \sum_{i=1}^{r} f_i e_i,$$

where $m = \left[ K : \mathbf{Q} \right]$. Then

$$Rp = \prod_{i=1}^{r} P_i^{e_i} \implies Sp = RSp = \left( \prod_{i=1}^{r} P_i^{e_i} \right) S = \prod_{i=1}^{r} (P_i S)^{e_i},$$

therefore

$$\|Sp\| = \prod_{i=1}^{r} \|P_i S\|^{e_i} = \prod_{i=1}^{r} \|P_i\|^{n_i e_i} = \prod_{i=1}^{r} (p^{f_i})^{n_i e_i}.$$

(The second equality follows from the fact that $S/S_{P_i}$ is a vector space over $R/P_i$ of dimension $n_i \leq n$.)

On the other hand, we have

$$\|Sp\| = |N_{L/\mathbf{Q}}(p)| = p^{nm},$$

because

$$[L : \mathbf{Q}] = [L : K][K : \mathbf{Q}] = nm.$$

If there exists $n_i < n$, then

$$\sum_{i=1}^{r} f_i n_i e_i < n \left( \sum_{i=1}^{r} f_i e_i \right) = nm,$$

a contradiction. Hence $n_i = n$, for all $P_i$, in particular, for $P$. We have shown that the dimension of $S/S_P$ over $R/P$ is $n$. If $V$ is a vector space of dimension $u$ over a finite field of $s$ elements, then $V$ has $s^u$ elements. As $S/S_P$ has $\|Sp\|$ elements and the dimension of $S/S_P$ over $R/P$ is $n$, $S/S_P$ has $\|P\|^n$ elements, i.e., $\|Sp\| = \|P\|^n$. This finishes the proof. \qed

We now prove the main theorem of this section, which we refer to as the principal theorem of ramification.

**Theorem 13.6** Let $K \subset L$ be number fields, with $[L : K] = n$, and $R$, $S$ the corresponding number rings. We suppose that $Q_1, \ldots, Q_s$ are the nonzero prime ideals in $S$ lying over the prime ideal $P$ of $R$ and we denote by $e_1, \ldots, e_s$ and $f_1, \ldots, f_s$ the corresponding ramification indices and inertial degrees. Then

$$\sum_{i=1}^{s} e_i f_i = n.$$

**Proof** We have

$$SP = \prod_{i=1}^{s} Q_i^{e_i} \implies \|Sp\| = \prod_{i=1}^{s} \|Q_i\|^{e_i} = \prod_{i=1}^{s} \|P\|^{f_i e_i}.$$

Also,

$$\|Sp\| = \|P\|^n,$$
therefore
\[
\sum_{i=1}^{s} e_i f_i = n.
\]
This ends the proof. \(\square\)

**Example** If \(L\) is a quadratique extension of \(\mathbb{Q}\), with number field \(S\), and \(p\) is a prime number, then there are three possible decompositions of \(pS\) into prime ideals:
\[
\mathcal{S}_P = \begin{cases}
  Q^2, & f(Q|p) = 1, \\
  Q, & f(Q|p) = 2, \\
  Q_1Q_2, & f(Q_1|p) = f(Q_2|p) = 1.
\end{cases}
\]

### 13.4 Normal extensions

Let us now suppose that \(K\) and \(L\) are number fields, with \(L\) a normal extension of \(K\). As \(\text{char } \mathbb{Q} = 0\), \(L\) is separable over \(\mathbb{Q}\). Using Proposition 3.5 we obtain that \(L\) is separable over \(K\). Hence \(L\) is a Galois extension of \(K\). As usual we set \(R = \mathcal{O}_K\) and \(S = \mathcal{O}_L\). If \(x \in S\), then there exists a monic polynomial \(f \in \mathbb{Z}[X]\) such that \(f(x) = 0\). However, \(\mathbb{Z} \subset R \subset K\), so the coefficients of \(f\) are fixed by any automorphism \(\sigma \in \text{Gal}(L/K)\), which implies that \(\sigma(x)\) is an algebraic number. Thus \(\sigma(x) \in \mathcal{O}_L = S\) and so \(\sigma(S) \subset S\). In the same way, \(\sigma^{-1}(S) \subset S\), which implies that \(S \subset \sigma(S)\), hence \(\sigma(S) = S\).

We now consider ideals in \(S\). Let \(Q\) be an ideal in \(S\). If \(x, y \in Q, a \in S\) and \(\sigma \in \text{Gal}(L/K)\), then
\[
\sigma(x) - \sigma(y) = \sigma(x - y) \in \sigma(Q)
\]
and
\[
a\sigma(x) = \sigma(a')\sigma(x) = \sigma(a'x) \in \sigma(Q),
\]
where \(a' = \sigma^{-1}(a) \in S\). Therefore \(\sigma(Q)\) is an ideal of \(S\).

Suppose now that \(Q\) is a prime ideal in \(S\). If \(x, y \in S\) and \(xy \in \sigma(Q)\), then
\[
\sigma^{-1}(xy) \in Q \implies \sigma^{-1}(x)\sigma^{-1}(y) \in Q \implies \sigma^{-1}(x) \in Q \text{ or } \sigma^{-1}(y) \in Q \implies x \in \sigma(Q) \text{ or } y \in \sigma(Q).
\]
As \(\sigma(Q) \neq S\), \(\sigma(Q)\) is a prime ideal.

If \(Q\) is a prime ideal in \(S\) lying over the prime ideal \(P\) in \(R\), then
\[
Q \supset SP \implies \sigma(Q) \supset \sigma(SP) = \sigma(S)\sigma(P) = S\sigma(P).
\]

Since \(P \subset R \subset K\), \(\sigma(P) = P\), so \(\sigma(Q)\) lies over \(P\). Thus we obtain an action \(\phi\) of the group \(\text{Gal}(L/K)\) on the set \(Q\) of nonzero prime ideals \(Q\) lying over the prime ideal \(P\):
\[
\phi: \text{Gal}(L/K) \times Q \to (\sigma, Q) \mapsto \sigma(Q).
\]

In fact, due to the normality of the extension \(L/K\), this action is transitive:

**Theorem 13.7** If \(Q\) and \(Q'\) are nonzero prime ideals in \(S\) lying over the prime ideal \(P\) in \(R\), then there exists \(\sigma \in \text{Gal}(L/K)\) such that \(\sigma(Q) = Q'\).
PROOF If this is not the case, then $\sigma(Q) \neq Q'$, for all $\sigma \in G = \text{Gal}(L/K)$. Let us suppose that $\sigma_1(Q), \ldots, \sigma_s(Q)$ are the distinct images of $Q$ under $G = \text{Gal}(L/K)$. (We may assume that $\sigma_1 = \text{id}_L$, so $Q = \sigma_1(Q)$.) The prime ideals $Q', \sigma_1(Q), \ldots, \sigma_s(Q)$ are coprime in pairs. By the Chinese remainder theorem (Theorem F.1), there is a solution $a \in S$ of the system of congruences

$$
\begin{align*}
x & \equiv 0 \pmod{Q'} \\
x & \equiv 1 \pmod{\sigma_1(Q)} \\
\vdots & \equiv \vdots \pmod{\vdots} \\
x & \equiv 1 \pmod{\sigma_s(Q)}.
\end{align*}
$$

Let us now consider $N_{L/K}(a)$. Corollary 10.3 ensures that

$$N_{L/K}(a) = \prod_{\sigma \in G} \sigma^{-1}(a).$$

Since $\text{id}_L \in G$ and $\sigma^{-1}(a) \in S$, we have

$$N_{L/K}(a) \in K \cap Q' = Q' \cap R.$$

As $Q'$ lies over $P$, $N_{L/K}(a) \notin P$.

On the other hand, $\sigma^{-1}(a) \notin Q$, for every $\sigma \in G$. Given that $Q$ is a prime ideal, $N_{L/K}(a) \notin Q$, which is a contradiction, because $P \subset S \subset Q$.

**Corollary 13.2** Let $K$ and $L$ be number fields with corresponding number rings $R$ and $S$. If $L$ is a normal extension of $K$, $P$ a nonzero prime ideal in $R$ and $Q$, $Q'$ nonzero prime ideals in $S$ lying over $P$, then

$$e(Q|P) = e(Q'|P) \quad \text{and} \quad f(Q|P) = f(Q'|P).$$

**PROOF** We may write

$$SP = Q^{e_1}Q^{e_2}Q_3^{e_3} \cdots Q_s^{e_s},$$

where $e_1 = e(Q|P)$, $e_2 = e(Q'|P)$, $Q_3, \ldots, Q_s$ are the other prime ideals lying over $P$ and $e_i = e(Q_i|P)$, for $i = 3, \ldots, s$. There exists $\sigma \in \text{Gal}(L/K)$ such that $\sigma(Q) = Q'$. We have

$$SP = \sigma(PS) = \sigma(Q)^{e_1} \sigma(Q')^{e_2} \sigma(Q_3)^{e_3} \cdots \sigma(Q_s)^{e_s} = Q'^{e_1} Q'^{e_2} \sigma(Q_3)^{e_3} \cdots \sigma(Q_s)^{e_s}.$$ 

However, we also have

$$SP = Q^{e_1}Q^{e_2}Q_3^{e_3} \cdots Q_s^{e_s}$$

As $Q$ is the only prime ideal whose image under $\sigma$ is $Q'$ and the decomposition of $SP$ into prime ideals is unique, we must have

$$Q'^{e_2} = Q^{e_1} \implies e_2 = e_1.$$

Now we show that $f(Q|P) = f(Q'|P)$. There exists $\sigma \in \text{Gal}(L/K)$ such that $\sigma(Q) = Q'$. The mapping $\sigma$ restricted to $S$ is a ring automorphism. We set $\phi = \pi \circ \sigma|_S$, where $\pi$ is the projection of $S$ onto $S/Q'$. Then

$$\text{Ker } \phi = \{ x \in S : \sigma(x) \in Q' \} = Q.$$ 

Hence

$$S/Q \simeq S/Q'.$$

and

$$[S/Q' : R/P] = [S/Q : S/Q][S/Q : R/P] = [S/Q : R/P],$$

177
i.e., \[ f(Q'|P) = f(Q|P), \]
as announced. \(\square\)

**Remark** From Corollary 13.2, if \(L\) is a normal extension of \(K\) and \(P\) is a nonzero prime ideal in \(R\), then \[ SP = (Q_1 \cdots Q_s)^e, \]
where \(e\) is the common ramification index of the prime ideals in \(S\) lying over \(P\).

**Example** The cyclotomic field \(\mathbb{Q} (\mu_n)\) is a normal extension of \(\mathbb{Q}\), because \(\mathbb{Q} (\mu_n)\) is the splitting field of the minimal polynomial \(m(\mu_n, \mathbb{Q})\). If \(p\) is a prime number and \(Q_1, \ldots, Q_s\) are the prime ideals in \(S = O_{\mathbb{Q} (\mu_n)}\) which lie over \(p\), then \(SP = (Q_1, \cdots, Q_s)^e\), where \(e\) is the common ramification index of the ideals \(Q_i\).

### 13.5 Ramified prime ideals

Let \(R \subset S\) be number rings, with respective number fields \(K\) and \(L\). We say that a prime ideal \(P\) in \(R\) is **ramified** in \(S\), if \(e(Q|P) > 1\) for some prime ideal \(Q\) in \(S\) lying over \(P\). This amounts to saying that \(SP\) is not squarefree. If \(p\) is a prime number, then we say that \(p\) is ramified in \(S\), if \(e(Q|P) > 1\), for some prime ideal \(Q\) lying over \((p)\). A prime ideal (resp. prime number) is unramified in \(S\), if it is not ramified in \(S\). It may occur that \(e(Q|P) = n\) (resp. \(e(Q|P) = n\)), where \([L : K] = n\); in this case we say that \(P\) (resp. \(p\)) is **totally ramified** in \(S\).

We recall that all integral bases of a number ring \(R\) have the same discriminant, which we note \(\text{disc}(R)\). We have seen that \(\text{disc}(R) \in \mathbb{Z}\). The discriminant of a number ring \(R\) helps us to determine whether a prime number \(p\) is ramified in \(R\).

**Theorem 13.8** Let \(L\) be an extension of \(\mathbb{Q}\) of degree \(n\). If \(S = O_L\) and \(p \in \mathbb{Z}\) a prime ramified in \(S\), then \(p/\text{disc}(S)\).

**Proof** Let \(Q\) be a prime ideal in \(S\) lying over \(p\) such that \(e(Q|P) > 1\). Then

\[ Sp = QI, \]
where \(I\) is an ideal of \(S\) divisible by all prime ideals lying over \(p\). We note \(\sigma_1, \ldots, \sigma_n\) the \(\mathbb{Q}\)-monomorphisms of \(L\) into an algebraic closure \(C\) of \(\mathbb{Q}\). (We may take the set of algebraic numbers \(A(C/\mathbb{Q})\) for \(C\).) From Section 5.1 we know that there is a finite extension \(N\) of \(L\) which is normal over \(\mathbb{Q}\). Now, using Theorem 3.2, we extend each \(\sigma_i\) to a monomorphism \(\bar{\sigma}_i\) from \(N\) into \(C\). As \(N\) is a normal extension of \(\mathbb{Q}\), from Proposition 5.2 we have \(\bar{\sigma}_i(N) = N\) and so \(\bar{\sigma}_i\) is an automorphism of \(N\).

Let \(\alpha_1, \ldots, \alpha_n\) be an integral basis of \(S\) and take \(\alpha \in I \setminus Sp\); \(\alpha\) belongs to every prime ideal of \(S\) lying over \(p\). We may write

\[ \alpha = m_1\alpha_1 + \cdots + m_n\alpha_n, \]
with \(m_i \in \mathbb{Z}\). If \(p|m_i\), for all \(i\), then \(\alpha \in pS\), a contradiction, so there exists an \(m_i\) such that \(p \nmid m_i\). Without loss of generality, let us suppose that \(i = 1\); then \(p \nmid m_1\). We set

\[ d = \text{disc}(S) = \text{disc}_{L/\mathbb{Q}}(\alpha_1, \ldots, \alpha_n). \]

178
Then, using Exercise 10.2 we see that
\[ \text{disc}_{L/Q}(\alpha, \alpha_2, \ldots, \alpha_n) = m_1^2d. \]
As \( p \nmid m_1 \), to show that \( p|d \) it is sufficient to prove that \( p|\text{disc}(\alpha, \alpha_2, \ldots, \alpha_n) \). This we will now do.

As \( \alpha \) belongs to every prime ideal in \( S \) lying over \( p \), \( \alpha \) must lie in every prime ideal in \( T = O_N \) lying over \( p \): if \( Q \) is such a prime ideal, then \( Q \supset Tp \) and so \( p \in Q \); if we set \( Q = Q \cap S \), then \( Q \) is a prime ideal in \( S \) lying over \( p \), so \( \alpha \in Q \subset \bar{Q} \). We now fix a prime ideal \( \bar{Q} \) in \( T \) lying over \( p \); we claim \( \overline{\sigma}(\alpha) \in \bar{Q} \) for every \( \mathbb{Q} \)-automorphism \( \overline{\sigma} \) of \( N \). We notice first that \( \overline{\sigma}^{-1}(\bar{Q}) \) is a prime ideal in \( T \) lying over \( p \), hence \( \alpha \in \overline{\sigma}^{-1}(\bar{Q}) \). It follows that \( \overline{\sigma}_i(\alpha) \in \bar{Q} \), for \( i = 1, \ldots, n \). Since \( C \) is an algebraic closure of \( L \), from the definition of the discriminant we see that \( \text{disc}_{L/Q}(\alpha, \alpha_2, \ldots, \alpha_n) \in \bar{Q} \).

However, the discriminant is an integer, so \( \text{disc}_{L/Q}(\alpha, \alpha_2, \ldots, \alpha_n) \in \bar{Q} \cap \mathbb{Z} = \mathbb{Z}p \). Therefore \( p|\text{disc}_{L/Q}(\alpha, \alpha_2, \ldots, \alpha_n) \). \( \square \)

**Exercise 13.3** Consider the quadratic number field \( K = \mathbb{Q}(\sqrt{d}) \), where \( d \) is squarefree. Show that if an odd prime number \( p \) is ramified in the number ring \( O_K \), then \( p \) divides \( d \).

**Corollary 13.3** Only finitely many primes in \( \mathbb{Z} \) are ramified in a given number ring \( S \).

**Proof** The discriminant of \( S \) has only a finite number of prime divisors. \( \square \)

We may extend this result.

**Corollary 13.4** Let \( R \) and \( S \) be number rings, with \( R \subset S \). Then only a finite number of prime ideals in \( R \) are ramified in \( S \).

**Proof** Let \( P \) be a prime ideal in \( R \) which is ramified in \( S \). Then there exists a prime ideal \( Q \) in \( S \) which lies over \( P \) and is such that \( e(Q|P) > 1 \). However, the prime ideal \( P \) lies over a unique prime number \( p \in \mathbb{Z} \) (Theorem 13.1). From Proposition 13.3, we have
\[ e(Q|p) = e(Q|P)e(P|p) > 1. \]

Corollary 13.3 states that there is only a finite number of such primes \( p \). Now, each such prime lies under a finite number of prime ideals in \( R \) (Theorem 13.1) and the result follows. \( \square \)

### 13.6 Decomposition and inertia groups

Let \( K \) and \( L \) be number fields, with \( L \) normal over \( K \). As \( L \) is a Galois extension of \( K \), we have \( n = [L : K] = |\text{Gal}(L/K)| \). Let \( R \) and \( S \) be the number rings of \( K \) and \( L \) respectively, i.e., \( R = O_K \) and \( S = O_L \), and \( P \) a prime ideal in \( R \). All the prime ideals \( Q \) lying over \( P \) have the same ramification index \( e \) and inertia degree \( f \). If there are \( r \) such prime ideals, then \( n = rf \).

For each prime ideal \( Q \) lying over \( P \) we define two subgroups of \( G = \text{Gal}(L/K) \):

- the decomposition group
  \[ D = D(Q|P) = \{ \sigma \in G \mid \sigma(Q) = Q \} \]
- the inertia group
  \[ E = E(Q|P) = \{ \sigma \in G \mid \sigma(\alpha) \equiv \alpha \text{ (mod } Q) , \forall \alpha \in S \} \]

179
It is clear that $D$ and $E$ are subgroups of $G$. Also, $E$ is a subgroup of $D$: for all $\sigma \in E$, we have
$$\sigma(\alpha) \equiv \alpha \mod Q, \ \forall \alpha \in S \implies \sigma(\alpha) \equiv \alpha \mod Q, \ \forall \alpha \in Q \implies \sigma(Q) \subset Q.$$ 
As $E$ is a subgroup of $G$, $\sigma^{-1} \in E$, so we also have
$$\sigma^{-1}(Q) \subset Q \implies Q \subset \sigma(Q).$$
Therefore
$$\sigma(Q) = Q.$$ 
The members $\sigma$ of $D$ induce elements $\bar{\sigma}$ of the Galois group $\bar{G} = Gal(S/Q, R/P)$ in a natural way. If we restrict $\sigma \in G$ to $S$, then we obtain an automorphism $\sigma|_S$ of $S$. We now set $\phi = \pi \circ \sigma|_S$, where $\pi$ is the projection of $S$ onto $S/Q$. As
$$\ker \phi = \{\alpha \in S : \sigma(\alpha) \in Q\} = Q,$$
the mapping
$$\bar{\sigma} : S/Q \longrightarrow S/Q, \alpha + Q \longmapsto \sigma(\alpha) + Q$$
is an automorphism. In addition, $\bar{\sigma}$ fixes $R/P$, so $\bar{\sigma} \in \bar{G} = Gal(S/Q, R/P)$.

It is not difficult to see that the mapping
$$\psi : D \longrightarrow \bar{G}, \sigma \longmapsto \bar{\sigma}$$
is a group homomorphism, whose kernel is $E$. It follows that $E$ is a normal subgroup of $D$ and $D/E$ is isomorphic to a subgroup of $\bar{G}$. However, from Proposition 13.10 proved below, $[L^E : L^D] = f = [S/Q, R/P]$ and $[S/Q, R/P] = |\bar{G}|$, because $S/Q$ is a Galois extension of $R/P$, being a finite extension of a finite field, hence $[L^E : L^D] = |\bar{G}|$. In addition, $[L^E : L^D] = [D/E]$, so $[D/E] = |\bar{G}|$ and it follows that the groups $D/E$ and $\bar{G}$ are isomorphic. From Theorem 7.9 the group $\bar{G}$ is cyclic (and generated by the Frobenius automorphism $Fr : x \longmapsto x^q$, where $q = |R/P|$), which implies that $D/E$ is also cyclic.

**Exercise 13.4** If $P \subset R$ is a prime ideal, then there is a finite number of ideals $Q_1, \ldots, Q_r \subset S$ lying over $P$. Corresponding to each $Q_i$, is a decomposition group $D_i$ and an inertia group $E_i$. Show that the decomposition (resp. inertia) groups are conjugate in the Galois group $Gal(L/K)$, if $L$ is a normal extension of $K$. Deduce that, if the Galois group is abelian, then there is only one decomposition (resp. inertia) group.

We now consider the fixed fields $L^D$ and $L^E$, called respectively the decomposition field and inertia field. We have the relations
$$K \subset L^D \subset L^E \subset L$$
and
$$R = O_K \subset S^D \subset S^E \subset S,$$
where $S^D = O_{L^D}$ and $S^E = O_{L^E}$. We also introduce two other prime ideals, namely $Q^D$ and $Q^E$, where $Q^D$ (resp. $Q^E$) is the unique prime ideal in $S^D$ (resp. $S^E$) lying under $Q$. Then
$$P \subset Q^D \subset Q^E \subset Q.$$ 
We aim now to consider the relation between the fields $K$, $L$, $L^D$ and $L^E$, in particular, to determine $[L^D : K]$, $[L^E : L^D]$ and $[L : L^D]$.
Proposition 13.9 We have
\[ [L^D : K] = r. \]

Proof: We define a mapping \( \phi \) from the set of left cosets of \( D \) into the set of prime ideals over \( P \) in \( S \) by
\[ \phi(\sigma D) = \sigma(Q). \]
We have
\[ \sigma(Q) = \tau(Q) \iff \tau^{-1}\sigma(Q) = Q \iff \tau^{-1} \sigma \in D \iff \sigma D = \tau D, \]
therefore \( \phi \) is well-defined and injective. From Theorem 13.7 \( \phi \) is also surjective, so \( \phi \) is a bijection. There are \( r \) prime ideals lying over \( P \), so \([G : D] = r\). However, from Theorem 6.6 \([L^D : K] = [G : D]\), hence \([L^D : K] = r\).

□

Using the multiplicativity of the degree, we obtain

Corollary 13.5 The degree
\[ [L : L^D] = ef. \]

Our next task is to show that \([L^E : L^D] = f\). To do so we need some preliminary results.

Lemma 13.3 We have
\[ f(Q|Q^E) = 1. \]

Proof: Since \( S/Q \) is a Galois extension of the finite field \( S^E/Q^E \), it is sufficient to prove that the Galois group \( \tilde{G} = Gal(S/Q|S^E/Q^E) \) is reduced to the identity. We take \( \theta \in S/Q \) and consider the polynomial
\[ f(X) = (-\theta + X)^m \in S/Q [X], \]
where \( m = |E| \). We claim that the coefficients of \( f \) belong to the subring of \( S/Q \)
\[ S_1 = \{ a + Q : a \in S^E \}. \]
To see this, first we notice that there exists \( a \in S \) such that \( \theta = a + Q \). We set
\[ g(X) = \prod_{\sigma \in E} (-\sigma(a) + X) \in L[X]. \]
In fact, \( g \in S^E[X] \): The coefficients of \( g \) are fixed by any element \( \sigma \in E \), so they belong to \( L^E \); in addition, as \( a \in S \), \( \sigma(a) \in S \), for all \( \sigma \in E \), hence the coefficients of \( g \) belong to \( S \); it follows that the coefficients of \( g \) belong to \( L^E \cap S = S^E \). If we now consider the coefficients of \( g \) modulo \( Q \), then we obtain a polynomial \( \tilde{g} \) with coefficients in \( S_1 \). However, this polynomial is precisely \( f \), hence the coefficients of \( f \) belong to \( S_1 \), as claimed.

Now we consider the ring homomorphism
\[ \psi : S^E \rightarrow S_1, x \mapsto x + Q. \]
The kernel of this mapping is \( S^E \cap Q = Q^E \), hence \( S^E/Q^E \simeq S^E/Q \). Therefore we may consider that the coefficients of \( f \) belong to \( S^E/Q \). If \( \sigma \in \tilde{G} \), then \( \sigma \) fixes the coefficients of \( f \), so \( \sigma(\theta) \) is a root of \( f \). As \( f \) has the unique root \( \theta \), we must have \( \sigma(\theta) = \theta \). We have shown that the only element in \( \tilde{G} \) is the identity, as required.

□

The prime ideal \( Q \) lies over \( Q^D \). This is the unique prime ideal in \( S \) with this property: Theorem 6.7 ensures that \( L \) is a finite Galois extension of \( L^D \). If \( Q' \) lies over \( Q^D \), then there exists \( \sigma \in Gal(L/L^D) \), such that \( \sigma(Q) \subset Q' \) (Theorem 13.7). However, Theorem 6.7 also ensures that \( Gal(L/L^D) = D \), so \( Q = \sigma(Q) \subset Q' \), which implies that \( Q = Q' \). We will use this observation to obtain our second preliminary result.

181
Lemma 13.4 We have
\[ e(Q^D | P) = f(Q^D | P) = 1. \]

Proof First we notice that
\[ ef = [L : L^D] = e(Q | Q^D) f(Q | Q^D), \]
because \( Q \) is the unique ideal in \( S \) lying over \( Q^D \). Also,
\[ e = e(Q | P) = e(Q | Q^D) e(Q^D | P) \Rightarrow e(Q | Q^D) \leq e. \]

In the same way,
\[ f(Q | Q^D) \leq f. \]

Hence
\[ e(Q | Q^D) = e \quad \text{and} \quad f(Q | Q^D) = f \]
and it follows that
\[ e(Q^D | P) = f(Q^D | P) = 1, \]
as claimed. \( \square \)

The third preliminary result is the following:

Corollary 13.6 For \( Q^E \) and \( Q^D \) we have
\[ f(Q^E | Q^D) = f. \]

Proof Using the multiplicativity of the inertial degree, we obtain
\[ f(Q | P) = f(Q | Q^E) f(Q^E | Q^D) f(Q^D | P) \Rightarrow f = 1 f(Q^E | Q^D) \Rightarrow f = f(Q^E | Q^D). \]

The result now follows from Lemma 13.3 and Lemma 13.4. \( \square \)

Now we are in a position to consider \([L^E : L^D]\)

Proposition 13.10 We have
\[ [L^E : L^D] = f. \]

Proof As \( Q^E \) lies over \( Q^D \), from Theorem 13.6 we have
\[ [L^E : L^D] \geq e(Q^E | Q^D) f(Q^E | Q^D). \]

and then, using Corollary 13.6, we obtain
\[ [L^E : L^D] \geq f. \]

We have seen that \( L \) is a Galois extension of \( L^D \), with \( D = Gal(L | L^D) \), and that \( E \) is a normal subgroup of \( D \), with \( D/E \) embedded in \( \tilde{G} = Gal(S/Q, R/P) \). Then Theorem 6.4 ensures that \( E = Gal(L | L^E) \); in addition, from Theorem 6.6 we obtain that \( L^E \) is a Galois extension of \( L^D \) and \( D/E \) is isomorphic to \( Gal(L^E / L^D) \). From this we deduce
\[ [L^E : L^D] = |Gal(L^E / L^D)| = |D/E| \leq |\tilde{G}|. \]

Moreover, \( |\tilde{G}| = f \), because \( S/Q \) is a finite extension of the finite field \( R/P \) and thus a Galois extension. This finishes the proof. \( \square \)

We can now easily obtain \([L : L^E]\). In fact,
Proposition 13.11

\[ [L : L^E] = e. \]

PROOF We have

\[ ef = [L : L^D] = [L : L^E][L^E : L^D] = [L : L^E]f \]

and the result follows.

13.7 Optimal properties of \( L^D \) and \( L^E \)

Let \( K \) and \( L \) be number fields with \( L \) normal over \( K \). The prime ideal \( Q \) lies over \( Q^D \). This is the unique such prime ideal in \( S \) with this property: If \( Q' \) is such a prime ideal, then there exists \( \sigma \in \text{Gal}(L^D) \) such that \( \sigma(Q) = Q' \). However, we have seen that \( \text{Gal}(L/L^D) = D \), so \( Q' = Q \).

This suggests the following question: If \( K' \) is a field intermediate between \( K \) and \( L \), is there a prime ideal \( Q' \subset R' = O_K \) such that \( Q \) is the unique prime ideal of \( S \) lying over \( Q' \)? We claim that any such field must contain \( L^D \), or, in other words, \( L^D \) is the smallest intermediate field with this property.

Theorem 13.9 Let \( L \) be a normal extension of \( K \). If \( K' \) is a field intermediate between \( K \) and \( L \) and there is a prime ideal \( Q' \subset R' \) such that \( Q \) is the unique prime ideal of \( S \) lying over \( Q' \), then \( L^D \subset K' \).

PROOF If \( K' \) is an intermediate field between \( K \) and \( L \), then there is a subgroup \( H \) of \( \text{Gal}(L/K) \) such that \( K' = L^H \). Suppose that \( Q \) is the unique prime ideal lying over \( Q' \). Every element \( \sigma \in H \) sends \( Q \) to a prime ideal lying under \( Q' \). As there is only one such prime ideal, \( H \subset D \), which implies that \( L^D \subset L^H = K' \).

We are going to consider another property of \( L^D \), but, before doing so, we must do some preliminary work. We suppose that \( K' \) is an intermediate field between \( K \) and \( L \). From Proposition 5.3, \( L \) is a normal (hence Galois) extension of \( K' \). We now set \( R' = O_{K'} \) and \( Q' = Q \cap R' \). Then \( Q' \) is the unique prime ideal in \( R' \) lying under \( Q \). Also, \( Q' \) lies over \( P \). We aim to replace \( K \) by \( K' \). We set

\[ D' = D(Q/Q') \quad \text{and} \quad E' = E(Q/Q'). \]

There is a subgroup \( H \) of the Galois group \( \text{Gal}(L/K) \) such that \( K' = L^H \). We have

\[ D' = \{ \sigma \in \text{Gal}(L/L^H) : \sigma(Q) = Q \} = \{ \sigma \in H : \sigma(Q) = Q \} = D \cap H \]

and

\[ E' = \{ \sigma \in \text{Gal}(L/L^H) : \sigma(\alpha) = \alpha(\mod Q), \ \forall \alpha \in S \} \]
\[ = \{ \sigma \in H : \sigma(\alpha) = \alpha(\mod Q), \ \forall \alpha \in S \} \]
\[ = E \cap H. \]

Now, from Theorem 6.9, \( L^{D'} = L^D K' \) and \( L^{E'} = L^E K' \).

We now consider the property of \( L^D \) referred to above. We restate Lemma 13.4 as a proposition:

Proposition 13.12

\[ e(Q^D|P) = f(Q^D|P) = 1. \]
This proposition suggests the following question: If $K'$ is a field intermediate between $K$ and $L$ and there is a prime ideal $Q' \subset R' = O_{K'}$ such that

$$e(Q'|P) = f(Q'|P) = 1,$$

what can we say about the relation between $K'$ and $L^D$? We claim that $L^D$ must contain such a field, or, in other words, $L^D$ is the largest intermediate field with this property.

**Theorem 13.10** Let $K$ and $L$ be number fields with $L$ normal over $K$. If $K'$ is a field intermediate between $K$ and $L$ such that the prime ideal $Q'$ in $R' = O_{K'}$ lying under $Q$ has the property

$$e(Q'|P) = f(Q'|P) = 1,$$

then $K' \subset L^D$.

**Proof** Since $Q$ lies over $Q'$ and $Q'$ over $P$, we notice that

$$e = e(Q|Q')e(Q'|P) = e(Q|Q') \quad \text{and} \quad f = f(Q|Q')f(Q'|P) = f(Q|Q').$$

Therefore, since $L$ is a normal extension of $K'$ (Proposition 5.3), from Corollary 13.5,

$$[L : L^D] = e(Q|Q')f(Q|Q') = ef = [L : L^D].$$

However, $L^D \subset L^{D'}$, which implies that $L^D = L^{D'} = L^D K'$ and so $K' \subset L^D$. This ends the proof. \(\square\)

We now turn to a property of $L^E$.

**Proposition 13.13** We have

$$e(Q^E|P) = 1.$$

**Proof** We notice that

$$e(Q|P) = e(Q^E|Q^D)e(Q^D|P) = e(Q^E|Q^D),$$

from Proposition 13.12. It remains to show that $e(Q^E|Q^D) = 1$. This can be derived from Corollary 13.6 and Proposition 13.10. We have

$$f = [L^E : L^D] = e(Q^E|Q^D)f(Q^E|Q^D) = e(Q^E|Q^D)f$$

hence $e(Q^E|Q^D) = 1$. \(\square\)

This property suggests the following question: If $K'$ is a field intermediate between $K$ and $L$ and there a prime ideal $Q' \subset R' = O_{K'}$ such that

$$e(Q'|P) = 1,$$

what can we say about the relation between $K'$ and $L^E$? We have seen that $K' \subset L^D$. We claim that $L^E$ must contain any intermediate field containing $K'$, or, in other words, $L^E$ is the largest intermediate field with this property.

**Theorem 13.11** Let $K$ and $L$ be number fields with $L$ normal over $K$. If $K'$ is a field intermediate between $K$ and $L$ and the prime ideal $Q'$ of $R' = O_{K'}$ lying under $Q$ is such that

$$e(Q'|P) = 1,$$

then $K' \subset L^E$.  

184
Proof We will use a procedure analogous to that used in the proof of Theorem 13.10. As in the proof of this theorem, we obtain $e(P'|P) = 1$ and $e = e(Q|Q')$, where $P' = Q \cap R'$. However, since $L$ is a normal extension of $K'$ (Proposition 5.3), using Proposition 13.11 we obtain

$$[L : L^E] = e(Q|Q') = e = [L : L^E].$$

Because $L^E \subset L^{E'}$, we have the equality $L^E = L^{E'} = L^E K'$, thus $K' \subset L^E$. This ends the proof. □

Remark It is interesting to compare Theorems 13.10 and 13.11. In the first case we obtain $K' \subset L^D$, which is stronger than $K' \subset L^E$, the result obtained in the second case, because $L^D \subset L^E$.

Non-ramification and complete splitting in composita

Let $K$, $L$ be number fields, with $L$ an extension (not necessarily normal) of $K$, and $R$ and $S$ the corresponding number rings. If $P$ is a nonzero prime ideal in $R$, then we say that $P$ splits completely in $S$, if $PS$ can be written as a product of $n = [K : L]$ distinct prime ideals in $S$. From Theorem 13.6 we have

$$
\sum_{i=1}^{n} e_i f_i = n \implies e_i = f_i = 1.
$$

Clearly, if $e_i = f_i = 1$, for all $i$, then $P$ splits completely in $S$.

We can compare this notion with that of non-ramification. If the ideal $P$ splits completely in $S$, then $P$ is unramified in $S$. However, the converse is false: We may have

$$SP = Q_1 \cdots Q_s,$$

with $s < n$ and certain $f_i > 1$. Non-ramification is thus weaker than complete splitting. In the following, if $F$ and $G$ are number fields, with $F \subset G$, and $Q$ is an ideal in $O_G$, then we will write $Q_F$ for $Q \cap O_F$, the unique prime ideal of $O_F$ lying under $Q$. If $Q$ is a prime ideal, then so is $Q_F$. (It should be noticed that $Q^D = Q_L$ and $Q^E = Q_L$.)

**Theorem 13.12** Let $K$, $L$ and $M$ be number fields, with $L$ and $M$ extensions of $K$, and $P$ a nonzero prime ideal in $O_K$ which is unramified (resp. splits completely) in $O_L$ and $O_M$. Then $P$ is unramified (resp. splits completely) in $O_{LM}$.

Proof We first consider the non-ramification. Suppose that $P$ is a nonzero prime ideal which is unramified in $O_L$ and $O_M$ and $Q'$ a prime ideal in $O_{LM}$ lying over $P$. We must show that $e(Q'|P) = 1$. As $LM$ is a finite extension of $K$, there exists a finite normal extension $N$ of $K$ containing $LM$ (see Section 5.1). Let $Q$ be a prime ideal in $O_N$ lying over $Q'$. Proposition 13.3 ensures that $Q$ also lies over $P$. We note $E$ the inertia group $E(Q|P)$, i.e.,

$$E(Q|P) = \{ \sigma \in \text{Gal}(N/K) : \sigma(\alpha) \equiv \alpha (\text{mod } Q), \forall \alpha \in O_N \}.$$ 

As $Q_L \cap O_K = P$ and $Q_M \cap O_K = P$, $Q_L$ and $Q_M$ lie over $P$. Given that $Q_L$ and $P_L$ are unramified over $P$, we have

$$e(Q_L|P) = e(Q_M|P) = 1.$$ 

From Theorem 13.11 $N^E$ contains both $L$ and $M$ and hence $LM$. As $Q$ is a prime ideal, so is $Q_{N^E}$. Then, using Proposition 13.14, we have

$$1 = e(Q_{N^E}|P) = e(Q_{N^E}|Q_{LM})e(Q_{LM}|P).$$
This implies that $e(Q_{LM}|P) = 1$, i.e., $e(Q'|P) = 1$.

We now consider the complete splitting. As we have seen, the nonzero prime ideal $P$ in $O_K$ splits completely in $O_{LM}$ if and only if, for every prime ideal $Q'$ in $O_{LM}$ lying over $P$, we have $e(Q'|P) = f(Q'|P) = 1$. As above we take a prime ideal $Q'$ in $O_{LM}$, let $N$ be a finite normal extension of $K$ containing $LM$ and $Q$ be a prime ideal in $N$ lying over $Q'$. Once again, $Q$ also lies over $P$. We note $D$ the decomposition group $D(Q|P)$, i.e.,

$$D(Q|P) = \{ \sigma \in \text{Gal}(N/K) : \sigma(Q) = Q \}.$$ 

We define $Q_L$ and $Q_M$ as above and so $Q_L$ and $Q_M$ lie over $P$. As $P$ splits completely in $O_L$ and $O_M$, we have

$$e(Q_L|P) = f(Q_L|P) = 1 \quad \text{and} \quad e(Q_M|P) = f(Q_M|P) = 1.$$ 

From Theorem 13.10, $N^D$ contains both $L$ and $M$, hence $LM$. Then, by Proposition 13.12

$$1 = e(Q_N^D|P) = e(Q_{NM}^D|Q_{LM})e(Q_{LM}|P) \quad \text{and} \quad 1 = f(Q_N^D|P) = f(Q_{NM}^D|Q_{LM})f(Q_{LM}|P),$$ 

and so

$$e(Q_{LM}|P) = f(Q_{LM}|P) = 1, \quad \text{i.e.,} \quad e(Q'|P) = f(Q'|P) = 1.$$ 

This finishes the proof. $\Box$

**Exercise 13.5** In the preceding proof, we take the normal closure $N$ of $K$ over $LM$. What is the reason for doing so?

**Corollary 13.7** Let $K$ and $L$ be number fields, with $K \subset L$, and $P$ a nonzero prime ideal in $O_K$. If $P$ is unramified or splits completely in $O_L$, then the same is true in a normal closure $N$ of $L$ over $K$.

**Proof** Let $P$ be a nonzero prime ideal in $O_K$. We first suppose that $P$ is unramified in $O_L$. We must show that, if $Q$ is a nonzero prime ideal in $O_N$ lying over $P$, then $e(Q|P) = 1$. If $\sigma \in \text{Gal}(N/K)$, then we have

$$O_LP = Q'_1 \cdots Q'_s \implies P\sigma(O_L) = \sigma(Q'_1) \cdots \sigma(Q'_s),$$

which means that $P$ is unramified in $O_{\sigma(L)}$. However, from Theorem 6.12, we know that

$$N = \prod_{\sigma \in \text{Gal}(N/K)} \sigma(L).$$

Applying Theorem 13.12 successively we obtain that $P$ is unramified in $O_N$.

We use an analogous argument to show that, if $P$ splits completely in $L$, then $P$ splits completely in $O_N$. $\Box$

**A criterion for complete splitting**

We begin with a preliminary result.

**Proposition 13.14** Let $K$, $L$ be number fields, with $L$ a normal extension of $K$. We suppose that $P$ is a prime ideal in $O_K$ and $Q$ a prime ideal in $O_L$ lying over $P$. In addition, we assume that the decomposition group $D = D(Q|P)$ is normal in $G = \text{Gal}(L/K)$. If $r$ is the number of distinct prime ideals in the splitting of $P$ in $O_L$, then $P$ splits into $r$ prime ideals in $O_{LM}$. 186
PROOF Since $D$ is normal in $G$, the corresponding field $L^D$ is a normal extension of $K$. From Lemma 13.4 we have

$$e(Q^D|P) = f(Q^D|P) = 1.$$  

Thus, using Corollary 13.2, for every prime ideal $P$ in $O_{L^D}$ lying over $P$

$$e(P|P) = f(P|P) = 1.$$  

If $\bar{r}$ is the number of distinct prime ideals $\bar{P}_i$ in the splitting of $P$ in $O_{L^D}$, then

$$\sum_{i=1}^{\bar{r}} e(\bar{P}_i|P)f(\bar{P}_i|P) = [L^D : K],$$

i.e., $\bar{r} = [L^D : K]$. However, from Proposition 13.9 we know that $[L^D : K] = r$, so $\bar{r} = r$ as claimed.

**Theorem 13.13** Let $Q$ be any ideal in $O_L$ lying over the prime ideal $P$ of $O_K$. Let us assume the conditions of Proposition 13.14 and let $K'$ be an intermediate field between $K$ and $L$. Then $P$ splits completely in $O_{K'}$ if and only if $K' \subset L^D(Q|P)$.

**Proof** If $P$ splits completely in $O_{K'}$, then

$$e(Q'|P) = f(Q'|P) = 1,$$  

where $Q'$ is the unique ideal of $O_{K'}$ lying under $Q$. ($Q'$ lies over $P$ and the relation (13.2) follows directly from the definition of complete splitting.) By Theorem 13.10 we have $K' \subset L^D$.

Now suppose that $K' \subset L^D|Q|P$. As in the proof of Proposition 13.14, Lemma 13.4 and Corollary 13.2 ensure that $P$ splits completely in $O_{L|Q}$. If $P'$ is a prime ideal in $O_{K'}$, lying over $P$, then $P'$ lies under some prime ideal $P$ in $O_{L|Q}$ lying over $P$. We have

$$e(P|P) = f(P|P) = 1 \implies e(P'|P) = f(P'|P) = 1,$$

Hence $P$ splits completely in $O_{K'}$. \qed

### 13.8 Existence of ramified prime numbers

In this section our goal is to establish a necessary and sufficient condition for the existence of a ramified prime number in a given number ring. We have already seen that, if $p$ is a prime number which is ramified in a number ring $R = O_K$, then $p$ divides $\text{disc}(R)$ (Theorem 13.8). We aim to show that this condition is also sufficient.

**Theorem 13.14** Let $K$ be a number field and $R = O_K$. Then the prime number $p$ is ramified in $R$ if and only if $p$ divides the discriminant of $R$.

**Proof** We have already shown that if $p$ is ramified in $R$, then $p|\text{disc}(R)$, so we only need to prove the converse. Let us suppose that $p|\text{disc}(R)$. We fix an integral basis $\alpha_1, \ldots, \alpha_n$ of $R$. Then, from Proposition 10.7,

$$\text{disc}(R) = |T_{K/Q}(\alpha_1, \alpha_j)|,$$

where $|T_{K/Q}(\alpha, \alpha_j)|$ is the determinant of the matrix $T = (T_{K/Q}(\alpha_i, \alpha_j))$. From the definition of the trace in Section 10.1 the elements $T_{K/Q}(\alpha_i, \alpha_j) \in \mathbb{Q}$. However, $\alpha_i \alpha_j \in O_K$, so $T_{K/Q}(\alpha_i, \alpha_j) \in \mathbb{Z}$ (Exercise 11.1). Working modulo $p$, i.e., considering these elements lying in $\mathbb{F}_p$ and, knowing
that \( \text{disc}(R) = 0 \) in \( \mathbf{F}_p \), we see that the rows of the matrix \( T \) are linearly dependent, i.e., there exist \( m_1, \ldots, m_n \in \mathbf{F}_p \), not all 0, such that

\[
m_1 \left( T_{K/Q}(\alpha_1 \alpha_1) \ldots T_{K/Q}(\alpha_1 \alpha_n) \right) + \cdots + m_n \left( T_{K/Q}(\alpha_n \alpha_1) \ldots T_{K/Q}(\alpha_n \alpha_n) \right) = (0, \ldots, 0).
\]

We may express this by saying that there exist integers \( m_1, \ldots, m_n \), not all divisible by \( p \), such that

\[
\sum_{i=1}^n T_{K/Q}(\alpha_i \alpha_j) m_i
\]

is divisible by \( p \), for \( j = 1, \ldots, n \). If we set \( \alpha = \sum_{i=1}^n m_i \alpha_i \), then

\[
p|T_{K/Q}(\alpha \beta_j),
\]

for \( j = 1, \ldots, n \), and it follows that \( p|T_{K/Q}(\alpha \beta) \), for any \( \beta \in R \), i.e., \( T_{K/Q}(R\alpha) \subset \mathbf{Z}_p \). Moreover, \( \alpha \in R \setminus pR \), since the integers \( m_1, \ldots, m_n \) are not all divisible by \( p \) and \((\alpha_1, \ldots, \alpha_n)\) is an integral basis of \( R \).

Let \( Q_1, \ldots, Q_s \) be the prime ideals in \( R \) involved in the decomposition of the ideal \( Rp \). Propositions 12.2 and 12.3 ensure that \( \cap_{t=1}^s Q_t = Q_1 \cdots Q_s \). If \( p \) is unramified in \( R \), then \( Rp = Q_1 \cdots Q_s \); thus, as \( \alpha \notin Rp \), there exists \( Q_t \) such that \( \alpha \notin Q_t \).

We now consider a normal closure \( N \) of \( K \) over \( \mathbf{Q} \). From Corollary 13.7, \( p \) is unramified in \( O_N = S \). Let \( Q' \) be a nonzero prime ideal in \( S \) lying over \( Q_i \). If \( \alpha \in Q' \), then \( \alpha \in Q' \cap R = Q_i \), a contradiction, thus \( \alpha \notin Q' \). We claim that \( T_{N/Q}(S\alpha) \subset \mathbf{Z}_p \). To see this, we apply Corollary 10.3:

\[
T_{N/Q}(S\alpha) = T_{K/Q} \circ T_{N/K}(S\alpha) = T_{K/Q} \left( T_{N/K}(S)\alpha \right) \subset T_{K/Q}(R\alpha) \subset \mathbf{Z}_p.
\]

As \( Q' \) lies over \( Q_i \) and \( Q_i \) lies over \( p \), \( Q' \) lies over \( p \). We take the complete set \( Q'_1, Q'_2, \ldots, Q'_{i} \) of nonzero prime ideals in \( S \) which lie over \( p \). From the Chinese remainder theorem (Theorem F.1), there is a solution \( \beta \in S \) of the system of equivalences

\[
\begin{align*}
x &\equiv 1 \pmod{Q'_i} \\
x &\equiv 0 \pmod{Q_j} \quad (j \neq i)
\end{align*}
\]

The element \( \beta \) lies in \( Q'_i \), for \( i = 2, \ldots, t \), but not in \( Q' \). We claim that

- \( T_{N/Q}(\alpha \beta \gamma) \in Q' \), for \( \gamma \in S \);
- \( \sigma(\alpha \beta \gamma) \in Q' \), for \( \gamma \in S \) and \( \sigma \in G \setminus D \),

where \( G = \text{Gal}(N/Q) \) and \( D = D(Q'|p) \). The first assertion is easy to prove. We only need to observe that \( \beta \gamma \in S \) and \( T_{N/Q}(S\alpha) \subset \mathbf{Z}_p \subset Q' \). The second assertion requires a little more work. First we notice that \( \sigma \in G \setminus D \) implies that \( \sigma(Q') \neq Q' \), or equivalently \( Q' \neq \sigma^{-1}(Q') \). As \( \sigma^{-1}(Q') \) lies over \( p \), \( \beta \in \sigma^{-1}(Q') \), which implies that \( \sigma(\beta) \in Q' \), which in turn implies that \( \sigma(\alpha \beta \gamma) \in Q' \).

We now claim that

\[
\sum_{\sigma \in D} \sigma(\alpha \beta \gamma) \in Q'
\]

for all \( \gamma \in S \). To see this, we first remark that from Corollary 10.3

\[
T_{N/Q}(\alpha \beta \gamma) = \sum_{\sigma \in G} \sigma(\alpha \beta \gamma).
\]

188
Then
\[ \sum_{\sigma \in D} \sigma(\alpha\beta\gamma) = T_{N/\mathbb{Q}}(\alpha\beta\gamma) - \sum_{\sigma \in G \setminus D} \sigma(\alpha\beta\gamma), \]
i.e., the difference of two elements in \( Q' \).

We may now finish the proof. The members \( \sigma \) of the subgroup \( D \) of \( G \) induce automorphisms \( \bar{\sigma} \) of \( S/\mathbb{Q}' \):
\[ \bar{\sigma}(x + \mathbb{Q}') = \sigma(x) + \mathbb{Q}'. \]
Reducing \( \alpha, \beta \) and \( \gamma \) modulo \( \mathbb{Q}' \), we obtain
\[ \sum_{\sigma \in D} \bar{\sigma}(\bar{\alpha}\bar{\beta}\bar{\gamma}) = 0, \]
for all \( \gamma \in S \). We have seen above that \( \alpha, \beta \notin \mathbb{Q}' \), so \( \bar{\alpha}\bar{\beta} \) is a nonzero member of the field \( S/\mathbb{Q}' \). As \( \gamma \) runs through all the elements of \( S \), \( \bar{\gamma} \) runs through all the elements of \( S/\mathbb{Q}' \). It follows that
\[ \sum_{\sigma \in D} \bar{\sigma}(\bar{x}) = 0, \]
for all \( \bar{x} \in S/\mathbb{Q}' \). Hence the automorphisms \( \bar{\sigma} \), with \( \sigma \in D \), are not independant, which contra-
dicts the corollary to Dedekind’s lemma (Corollary 8.1). The supposition that \( p \) is unramified led us to this contradiction, hence \( p \) must be ramified.

\[ \square \]

**Remark** We will show in the next chapter that, if \( K \neq \mathbb{Q} \), then \( |\text{disc}(R)| > 1 \). Thus, in this case there exists a prime number \( p \) which divides \( \text{disc}(R) \). Consequently, Theorem 13.14 ensures the existence of a ramified prime number. More generally, if \( K \subset L \) are number fields, then there exists a prime ideal in \( \mathcal{O}_K \) which ramifies in \( \mathcal{O}_L \). To see this, it suffices to consider any prime ideal in \( \mathcal{O}_K \) in the decomposition of \( \mathcal{O}_K p \), where \( p | \text{disc}(O_L) \).

### 13.9 Prime decomposition in cyclotomic number rings

Let \( p \) be a prime number, \( s \) a positive integer and \( \zeta = e^{2\pi i/s} \). We will be interested in the decomposition of a prime \( q \) in the number ring of the cyclotomic field \( K = \mathbb{Q}(\zeta) \). As \( K \) is normal over \( \mathbb{Q} \) we may write
\[ \mathcal{O}_K q = (Q_1 \cdots Q_r)^c, \]
where the \( Q_i \) are prime ideals in \( \mathcal{O}_K \).

We will first consider the case where \( q = p \). In the proof of Proposition 11.10 we saw that
\[ \mathcal{O}_{Kp} = \mathcal{O}_K(1 - \zeta)^{\phi(p')} = (\mathcal{O}_K(1 - \zeta))^{\phi(p')} \quad (13.3) \]
and
\[ N_{K/\mathbb{Q}}(1 - \zeta) = p. \]
From Theorem 13.4
\[ N_{K/\mathbb{Q}}(1 - \zeta) = \|\mathcal{O}_K(1 - \zeta)\|, \]

hence \( \|\mathcal{O}_K(1 - \zeta)\| = p. \) However, from Proposition 13.4, the principal ideal \( \mathcal{O}_K(1 - \zeta) \) is a prime ideal, therefore the expression (13.3) is the decomposition of \( \mathcal{O}_{Kp} \) into prime ideals.
We now turn to the case where \( q \neq p \). This is more difficult. From Theorem 11.15 the discriminant of \( O_K \) is a power of \( p \). As \( q \neq p \), \( q \) does not divide the discriminant, so, by Theorem 13.14, \( q \) is not ramified in \( O_K \). This implies that the decomposition has the form

\[
O_K q = Q_1 \cdots Q_r,
\]

where the \( Q_i \) are prime ideals in \( O_K \). We now aim to determine the value of \( r \).

We recall that \( O_K = \mathbb{Z}[\zeta] \). For \( i = 1, \ldots, r \), since \( Q_i | O_K q \), we have \( Q_i \supset O_K q = \mathbb{Z}[\zeta]q \) and it follows that \( Q_i \) lies over \( \mathbb{Z}q \). From Corollary 13.2, the inertial degrees \( f(Q_i | q) \) all have the same value. If \( f \) is the common value of the inertial degrees, then we can write

\[
rf = \phi(p^s) = p^{s-1}(p - 1),
\]

where \( \phi \) denotes the Euler totient function. We claim that \( f \) is the order of \( q \) in the multiplicative group \( \mathbb{Z}^*_p \).

Let \( \bar{Q} \) be one of the \( Q_i \). Then \( \mathbb{Z}[\zeta] / \bar{Q} \) is isomorphic to \( \mathbb{F}_{p^f} \), with subfield \( \mathbb{F}_q \). (This is obtained from the mapping \( \phi \) defined just before Proposition 13.3.) We may identify the elements of \( \mathbb{F}_{p^f} \) with the cosets of \( \bar{Q} \), which we will write in the usual way, i.e., \( \bar{a} = a + \bar{Q} \). If \( a \in \mathbb{Z} \), then \( \bar{a} \in \mathbb{F}_q \) and from this it follows that \( \mathbb{F}_{p^f} = \mathbb{F}_q(\zeta) \). This implies that an element of the Galois group \( \bar{G} = \text{Gal}(\mathbb{F}_{p^f} / \mathbb{F}_q) \) is determined by its value at \( \zeta \).

Moreover, from Theorem 7.9, \( \bar{G} \) is cyclic and generated by the Frobenius automorphism \( \text{Fr} : x \mapsto x^q \). Since \( \mathbb{F}_{p^f} = \mathbb{F}_q(\zeta) \), the Frobenius automorphism, is determined by its value at \( \zeta \).

Let \( f' \) be the order of \( q \) in \( \mathbb{Z}^*_p \). Then

\[
\text{Fr}^{f'}(\zeta) = \bar{\zeta}^{q^{f'}} = \bar{\zeta}^{1 + kf'},
\]

for some \( k \in \mathbb{N}^* \). Therefore \( \text{Fr}^{f'}(\zeta) = \bar{\zeta} \), which implies that \( f | f' \).

We now show that \( f' | f \). If \( q^{f'} \equiv 1 \pmod{p^s} \), then \( f' | f \), so this is what we will show. We set

\[
q^f \equiv a \pmod{p^s},
\]

with \( a \in \{1, \ldots, p^s - 1\} \). Suppose that \( a > 1 \). Then

\[
\zeta^{q^f} = \zeta^a \implies \bar{\zeta}^{q^f} = \bar{\zeta}^a.
\]

However, from equation 13.5,

\[
\bar{\zeta}^{q^f} = \bar{\bar{\zeta}}^a = \bar{\zeta}^a,
\]

hence

\[
\bar{\zeta}^a = \bar{\zeta} \implies \bar{\zeta}^a - 1 = \bar{1} \implies 1 - \zeta^{-a} \in \bar{Q}.
\]

On the other hand we have

\[
-1 + X^{p^s} = \prod_{i=0}^{p^s-1} (-\zeta^i + X) \implies \prod_{i=1}^{p^s-1} (-\zeta^i + X) = \frac{-1 + X^{p^s}}{-1 + X} = 1 + X + \cdots + X^{p^s-1}.
\]

Noting \( g(X) \) the last expression on the right-hand side, we obtain

\[
\prod_{i=1}^{p^s-1} (-\zeta^i + 1) = g(1) = p^s.
\]
Since one of the factors in the expression on the left-hand side of the equation is \(1 - \zeta^{-1}\) and all the factors are in \(O_K\), we see that \(p^s \in Q\). This means that \(Q\) contains both \(p^s\) and \(q\), which are coprime. Hence \(1 \in Q\), a contradiction. Therefore \(a = 1\) and it follows that

\[ q^f \equiv 1 \pmod{p^s}, \]

as required. To conclude, we have shown that \(f\) is the order of \(q\) in \(\mathbb{Z}_{p^s}^\times\), as claimed.

To conclude, from (13.3) we obtain

\[ r = \frac{p^{s-1}(p-1)}{f}, \]

where \(f\) is the order of \(q\) in \(\mathbb{Z}_{p^s}^\times\).

**Remark** Further on, in Chapter 18, we will reconsider the question of the decomposition of a prime number in a number ring, but in a more general context.

### 13.10 Higher ramification groups

Let \(K\) and \(L\) be number fields, with \(L\) a finite normal extension of \(K\). We set \(R = O_K\), \(S = O_L\) and let \(P \subset R\), \(Q \subset S\) be prime ideals with \(Q\) lying over \(P\). We recall the definition of the inertia group:

\[ E = E(Q|P) = \{ \sigma \in G : \sigma(\alpha) \equiv \alpha (\text{mod } Q) \forall \alpha \in S\}, \]

where \(G = \text{Gal}(L/K)\). We now extend this definition. For \(m \in \mathbb{N}\), we set

\[ V_m = \{ \sigma \in G : \sigma(\alpha) \equiv \alpha (\text{mod } Q^{m+1}) \forall \alpha \in S\}. \]

Thus \(V_0 = E\). The \(V_m\) form a descending chain of subgroups of the decomposition group \(D = D(Q|P)\) and are called *ramification groups*.

We recall the Krull Intersection Theorem:

**Theorem 13.15** If \(R\) is a commutative noetherian domain and \(I\) a proper ideal in \(R\), then

\[ \cap_{m=1}^{\infty} I^m = \{0\}. \]

**Proposition 13.15** The groups \(V_m\) are normal subgroups of \(D\) and their intersection is the identity.

**Proof** Let \(\sigma \in V_m\) and \(\tau \in D\). Then, for \(\alpha \in S\), we have

\[ \sigma \tau(\alpha) = \tau(\alpha) + x \]

with \(x \in Q^{m+1}\). This implies that

\[ \tau^{-1} \sigma \tau(\alpha) = \alpha + \tau^{-1}(x). \]

Since \(\tau^{-1}Q = Q\) and \(x \in Q^{m+1}\), \(\tau^{-1}(x) \in Q^{m+1}\), thus

\[ \tau^{-1} \sigma \tau(\alpha) \equiv \alpha (\text{mod } Q^{m+1}), \]

and it follows that \(V_m\) is normal in \(D\).
As $S$ is a noetherian domain, from Theorem 13.15, $\cap_{m=1}^{\infty}Q^m = \{0\}$. If $\sigma \in \cap_{m=0}^{\infty}V_m$ and $\alpha \in S$, then
\[ \sigma(\alpha) - \alpha \in \cap_{m=1}^{\infty}Q^m = \{0\} \implies \sigma(\alpha) = \alpha. \]

Therefore $\sigma$ is the identity on $S$ and consequently on $L$, because $L$ is the field of fractions of $S$.

\[ \square \]

**Corollary 13.8** There exists $n \geq 0$ such that $V_m$ is reduced to the identity for $m \geq n$.

**PROOF** As $D$ is finite, so are the subgroups $V_m$ and the chain must be stationary after a certain point, i.e., there exists $n$ such that $V_m = V_n$, for $m \geq n$. If $V_m$ is not reduced to the identity for $m \geq n$, then the intersection of the groups $V_m$ must contain elements other than the identity, which is a contradiction. Therefore, for $m \geq n$, $V_m$ is reduced to the identity.

We recall that $S^E$ is the number ring of $L^E$, i.e., $S^E = O_{L^E}$, and that $Q^E$ is the unique prime ideal in $S^E$ lying under $Q$. We now consider the localizations $S_Q$ and $S_{Q^E}$. These rings are both Dedekind domains, being localizations of Dedekind domains (Theorem 12.9). They are also local rings with respective unique maximal ideals $S_Q$ and $S_{Q^E}$ (Theorem 12.10). From Theorem 12.11 these localizations are PIDs.

If $\frac{a}{s} \in S_{Q^E}$, then $s \in S$, because $S^E \subset S$. In addition, $u \notin Q$ (If $u \in Q$, then $u \in S^E \cap Q = Q^E$, a contradiction.) Hence $S_{Q^E} \subset S_Q$, and we may consider $S_Q$ to be a $S_{Q^E}$-module. Let $t$ be a generator of the principal ideal $S_Q$. We may suppose that $t \in S$: if $t' = \frac{a}{s}$ is a generator, then so is $t$.

**Theorem 13.16** The module $S_Q$ is a free module over $S_{Q^E}$, with basis $B = \{1, t, \ldots, t^{e-1}\}$, where $e = [L : L^E]$.

**PROOF** Our first step is to show that if $a$ is a nonzero element of $L^E$, then there exists $s \in Z$ such that $S_Qa = S_Q Q^e$. Let us write $L_Q$ for the fraction field of $S_Q$ and $L_{Q^E}$ for that of $S_{Q^E}$. Then $L^E \subset L \subset L_Q$ and so any nonzero element $a$ of $L^E$ generates a nonzero fractional ideal of $S_Q$, which we may write $S_Qa$. We aim to study the decomposition of $S_Qa$ into prime ideals in $S_Q$. Since $L^E \subset L_{Q^E}$, $a$ also generates a fractional ideal of $S_{Q^E}$, namely $S_{Q^E}a$. From Theorem 12.11 there exists $s \in Z$ such that
\[ S_{Q^E}a = (S_{Q^E}Q^E)^s = S_{Q^E}Q^Es, \]
and so, using the fact that $S_{Q^E}$ is contained in $S_Q$, we obtain
\[ S_Qa = S_QS_{Q^E}a = S_Q(S_{Q^E}Q^Es) = S_QQ^Es. \]

Now, using the inclusion of $S$ in $S_Q$, we have
\[ S_QQ^Es = S_Q S(Q^Es) = S_Q(SQ^E)^s. \]

Since $Q^E$ lies over $Q^D$ and $Q$ is the unique prime ideal of $S$ lying over $Q^D$ (see Section 13.7), $Q$ is the unique prime ideal of $S$ lying over $Q^E$: $SQ^E$ is a power of $Q$. Taking into account Theorem 13.6, with $K = L^E$, and then Lemma 13.3 and Proposition 13.11, we obtain $SQ^E = Q^s$. Finally, we have shown that, for any nonzero element $a$ in $L^E$, there exists $s \in Z$ such that $S_Qa = S_Q Q^es$.

Our next step is to show that the elements $1, t, \ldots, t^{e-1}$ form a basis of $L$ over $L^E$. As $[L : L^E] = e$, it is sufficient to prove that these elements are linearly independent over $L^E$.

192
Suppose that \( x = \sum_{j=0}^{e-1} a_j t^j \), with \( a_j \in L^E \) and some \( a_j \neq 0 \). If \( 0 \leq k, l \leq e - 1 \), with \( k \neq l \), and \( a_k \neq 0, a_l \neq 0 \), then we claim that \( s_k e + k \neq s_l e + l \), where

\[ S_Q a_k = S_Q Q^{e_k} \quad \text{and} \quad S_Q a_l = S_Q Q^{e_l}. \]

If not, then

\[ 0 \neq k - l = e(s_l - s_k), \]

which is impossible, because \( |k - l| < e \). We now set

\[ m = \min \{es_j + j : a_j \neq 0, S_Q a_j = S_Q Q^{e_j} \}. \]

Let \( i \) be such that \( m = es_i + i \); then, if \( 0 \leq j < e \) and \( a_j \neq 0 \), there exists \( \alpha_j \in S_Q \) such that \( a_j = \alpha_j t^{es_i} \). Therefore there exists \( \beta \in S_Q \) such that

\[ x = \sum_{j, \alpha_j \neq 0} \alpha_j t^{es_i + j} = tm(\alpha_i + t\beta). \]

If \( \alpha_i \in S_Q \), then \( a_i = t^{es_i} a_i \), with \( u \in S_Q \). This implies that

\[ (S_Q Q)^{s_i} = S_Q a_i \subset (S_Q Q)^{s_i + 1}, \]

which is not possible. Hence \( \alpha_i \notin S_Q \) and it follows that \( \alpha_i + t\beta \notin S_Q \). Thus \( \alpha_i + t\beta \neq 0 \) and so \( x \neq 0 \). We have shown that the set \( \{1, t, \ldots, t^{e-1}\} \) is independant.

At this point we should also notice that \( S_Q x = S_Q Q^m \). Indeed, as \( S_Q \) is a local ring, its maximal ideal \( S_Q \) is composed of its nonunits. Hence \( \alpha_i + t\beta \) is a unit and so

\[ S_Q x = S_Q t^m = S_Q Q^m. \]

The final step is to show that \( B \) is also a basis of the \( S_{Q\bar{\mu}}^E \)-module \( S_Q \). Suppose that there exist \( b_0, b_1, \ldots, b_{e-1} \in S_{Q\bar{\mu}}^E \) such that \( \sum_{j=0}^{e-1} b_j t^j = 0 \). As \( S_{Q\bar{\mu}}^E \) is included in \( L^E \) and we have shown that \( B \) is an independant set over \( L^E \), the \( b_j \) all have the value 0, so \( B \) is an independant set over \( S_{Q\bar{\mu}}^E \).

We must now show that \( B \) is a generating set of the \( S_{Q\bar{\mu}}^E \)-module \( S_Q \). Let \( x \) be a nonzero element of \( S_Q \). As \( S_Q \) is included in \( L \), we may write \( x = \sum_{j=0}^{e-1} a_j t^j \), where \( a_j \in L^E \), for all \( j \), and at least one \( a_j \) is nonzero. We claim that each \( a_j \) belongs to \( S_{Q\bar{\mu}}^E \). Looking at the beginning of the proof, we notice that, if \( a_j \neq 0 \), then there is an integer \( s_j \) such that the fractional ideal \( S_{Q\bar{\mu}}^E a_j = (S_{Q\bar{\mu}}^E Q^E)^{s_j} \). This is the decomposition of this fractional ideal into prime ideals of \( S_{Q\bar{\mu}}^E \).

In addition, we have shown that \( S_Q x = (S_Q Q)^m \) is the decomposition into prime ideals of \( S_Q \) of the fractional ideal \( S_Q x \). As \( x \in S_Q \), \( S_Q x \) is an integral ideal of \( S_Q \) and so \( m \geq 0 \) (Corollary 12.9). However,

\[ m = \min \{es_j + j : a_j \neq 0, S_Q a_j = S_Q Q^{es_j} \}, \]

so, if \( a_j \neq 0 \), then \( es_j + j \geq 0 \), which implies that \( s_j \geq -\frac{1}{e} > -1 \). Therefore \( s_j \geq 0 \), because \( s_j \) is an integer. It follows that \( S_{Q\bar{\mu}}^E a_j \) is an ideal of \( S_{Q\bar{\mu}}^E \), because \( S_{Q\bar{\mu}}^E a_j = (S_{Q\bar{\mu}}^E Q^E)^{s_j} \), and so \( a_j \in S_{Q\bar{\mu}}^E \). We have shown that \( B \) is a generating set of \( S_Q \) as a \( S_{Q\bar{\mu}}^E \)-module. This finishes the proof. \( \square \)

We continue our study of the ramification groups using a generator \( t \in S \) of the principal ideal \( S_Q \). We notice that \( t \in S \subset L \), so it makes sense to write \( \sigma(t) \) for any automorphism \( \sigma \in Gal(L/K) \).
Proposition 13.16 For $i = 0, 1, 2, \ldots,$

$$V_i = \{ \sigma \in E : \sigma(t) - t \in S_Q Q^{i+1} \}.$$

**Proof** If $\sigma \in V_i,$ then $\sigma \in E$ and $\sigma(t) - t \in Q^{i+1},$ since $t \in S.$ However, $Q^{i+1} \subset S_Q Q^{i+1},$ thus $\sigma(t) - t \in S_Q Q^{i+1}.$

Now suppose that $\sigma \in E$ and $\sigma(t) - t \in S_Q Q^{i+1}.$ If $x \in S,$ then we may consider that $x \in S_Q$ and so we can write $x = \sum_{j=0}^{e-1} a_j t^j,$ with $a_j \in S_{Q^E}$ (Theorem 13.15), hence

$$\sigma(x) - x = \sum_{j=0}^{e-1} a_j (\sigma(t)^j - t^j),$$

because the $a_j$ are fixed by the automorphisms of $E.$ (Indeed, $a_j \in S_{Q^E}$ and $S_{Q^E} \subset S^E \subset L^E.$)

Also, $\sigma(t) - t | \sigma(t)^j - t^j$ in $S,$ i.e., $\sigma(t)^j - t^j = s_j (\sigma(t) - t),$ for some $s_j \in S.$ As both $S_{Q^E}$ and $S$ are included in $S_Q,$

$$\sum_{j=0}^{e-1} a_j (\sigma(t)^j - t^j) \in S_Q Q^{i+1}$$

Given that $x \in S,$ we now have

$$\sigma(x) - x \in S_Q Q^{i+1} \cap S = Q^{i+1},$$

where we have used Theorem 12.12 for the equality. This ends the proof. \qed

We have seen that the ramification groups $V_i$ form a sequence of normal subgroups of the inertial group $E.$ As $V_{i+1} \subset V_i,$ we have a sequence

$$E = V_0 \triangleright V_1 \triangleright V_2 \triangleright \cdots$$

We also know that after a certain point $V_{i+1} = V_i,$ so we may consider the sequence to be finite. We are now interested in the factor groups $V_i/V_{i+1}.$

**Theorem 13.17** There exists a group monomorphism from $E/V_1$ into $S/Q^\times.$ Thus $E/V_1$ is a cyclic group whose order is coprime to $p,$ where $Q \cap \mathbb{Z} = \mathbb{Z}p.$

**Proof** Let $t \in S$ be a generator of the principal ideal $S_Q Q,$ so $t \in S \cap S_Q Q = Q$ (Theorem 12.12). If $\sigma \in E,$ then $\sigma \in D,$ which implies that $\sigma(t) \in Q,$ because $t \in Q.$ As $Q \subset S_Q Q,$ there exists $x_\sigma \in S_Q$ such that

$$\sigma(t) = x_\sigma t.$$  

From Exercise 12.8 we may suppose that $S_Q$ as a subset of $L,$ i.e., we consider $x = \frac{t}{n} \in S_Q$ as an element of $L.$ This permits us to induce a mapping $\sigma'$ on $S_Q$ from $\sigma \in E$ by setting $\sigma'(x) = \frac{\sigma(x)}{\sigma(t)} \in L.$ Clearly, $\sigma(r), \sigma(u) \in S.$ It is elementary to check that $\sigma'$ is an automorphism of $S_Q.$ We should also notice that, since $\sigma \in E,$ for all $x \in S_Q,$

$$\sigma'(x) \equiv x \pmod{S_Q Q}.$$

Indeed, there exists $q \in Q$ such that $\sigma(r) = r + q$ and so

$$\sigma'(x) = \frac{\sigma(r)}{\sigma(u)} = \frac{r + q}{u + q'k} = \frac{r}{u} - \frac{rq' - uq}{u(u + q')} = x + q_1,$$

194
with \( q_1 \in S_Q Q \).

To simplify the notation, from here on we will write \( \sigma \) for \( \sigma' \). Our next step is to show that \( x_\sigma \notin S_Q Q \). As \( \sigma^{-1} \in E \), there exists \( x_{\sigma^{-1}} \in S_Q \) such that

\[
\sigma^{-1}(t) = x_{\sigma^{-1}} t.
\]

Then

\[
t = \sigma(\sigma^{-1}(t)) = \sigma(x_{\sigma^{-1}}) = \sigma(x_{\sigma^{-1}}) \sigma(t) = \sigma(x_{\sigma^{-1}}) x_\sigma t.
\]

As \( S_Q \) is an integral domain, we have

\[
1 = \sigma(x_{\sigma^{-1}}) x_\sigma,
\]

so \( x_\sigma \) is invertible in \( S_Q \), which implies that \( x_\sigma \notin S_Q Q \), because \( S_Q Q \) is a proper ideal of \( S_Q \).

From Corollary 12.10, there is an isomorphism \( \phi \) from \( S_Q Q \) onto \( S/Q \). Noting \( \bar{x}_\sigma \), the image \( \phi(x_\sigma + S_Q Q) \), we have \( x_\sigma \neq 0 \), because \( x_\sigma \notin S_Q Q \). We now define a mapping \( \theta : E \longrightarrow S/Q^\times \) by

\[
\theta(\sigma) = \bar{x}_\sigma.
\]

We consider the properties of \( \theta \). First we notice that \( \theta \) is a group homomorphism: If \( \sigma, \tau \in E \), \( \sigma(t) = x_\sigma t \) and \( \tau(t) = x_\tau t \), then

\[
\sigma \tau(t) = \sigma(x_\tau t) = \sigma(x_\tau) \sigma(t) = (x_\tau + vt)x_\sigma t = (x_\tau x_\sigma + vx_\sigma t)t,
\]

where \( v \in S_Q \), therefore

\[
\theta(\sigma \tau) = \bar{x}_\tau x_\sigma + vx_\sigma t = \bar{x}_\tau x_\sigma = \theta(\sigma) \theta(\tau),
\]

so \( \theta \) is a homomorphism. We claim that the kernel of \( \theta \) is \( V_1 \). To establish this we use Proposition 13.16. If \( \sigma \in V_1 \), then

\[
\sigma(t) - t \in S_Q Q^2 \implies \sigma(t) = t + vt^2 = (1 + vt)t \implies \theta(\sigma) = \bar{1} + \bar{v}t = \bar{1},
\]

where \( v \in S_Q \). Hence \( \sigma \in \text{Ker } \theta \). On the other hand, if \( \sigma \in \text{Ker } \theta \), then \( \theta(\sigma) = \bar{1} \) and we have

\[
\bar{x}_\sigma = \bar{1} \implies \sigma(t) = x_\sigma t - t = (1 + vt)t - t = vt^2,
\]

where \( v \in S_Q \). It follows that \( \sigma \in V_1 \). We have shown that \( V_1 = \text{Ker } \theta \).

As \( V_1 \) is the kernel of \( \theta \), the quotient group \( E/V_1 \) is isomorphic to a subgroup of \( S/Q^\times \), which is the group of nonzero elements of the finite field \( S/Q \). From Corollary 3.3, \( S/Q^\times \) is cyclic and so \( E/V_1 \) is cyclic, being isomorphic to a subgroup of a cyclic group.

There exists a unique prime number \( p \) such that \( Q \cap Z = pZ \). As \( pZ \subset Q \), we have \( p \in Q \), so the characteristic of \( S/Q \) is \( p \). This implies that the prime field of \( S/Q \) is \( F_p \) and it follows that \( |S/Q| = p^n \), for some positive integer \( n \). Hence \( |S/Q^\times| = p^n - 1 \). As \( |E/V_1| \) divides \( p^n - 1 \), \( |E/V_1| \) must be coprime to \( p \).

Remark In the proof of the theorem we chose a particular generator \( t \in S \) of \( S_Q Q \). In fact, we obtain the same mapping \( \theta \) if we choose another such generator \( t' \). First we notice that \( t' = at \), where \( a \in S_Q^\times \). This implies that \( a \notin S_Q Q \). Then we have

\[
\sigma(t') = x_\sigma t' = x_\sigma at.
\]
As we saw in the proof of Theorem 13.17, if \( x \in S_Q \) and \( \sigma \in E \), then \( \sigma(x) \equiv x(\text{mod } S_Q) \), so there exists \( q \in S_QQ \) such that \( \sigma(a) = a + q = a + vt \), with \( v \in S_Q \). Hence

\[
x'_\sigma = \sigma(at) = \sigma(a)\sigma(t) = (a + vt)x_\sigma t
\]

\[
\Rightarrow x'_\sigma a = (a + vt)x_\sigma
\]

\[
\Rightarrow a\tilde{x}_\sigma = a\tilde{x}'_\sigma \Rightarrow \tilde{x}'_\sigma = \tilde{x}_\sigma,
\]

because \( S_Q/S_QQ \) is a field and \( a \neq 0 \). Therefore the value of \( \theta(\sigma) \) is unaltered by choosing another generator in \( S \) of \( S_Q \).

We now consider the quotient groups \( V_i/V_{i+1} \), with \( i \geq 1 \).

**Theorem 13.18** There exists a group monomorphism from \( V_i/V_{i+1} \) into the additive group of the field \( S/Q \). Hence \( V_i/V_{i+1} \) is an abelian \( p \)-group, where \( Q \cap \mathbb{Z} = \mathbb{Z}_p \).

**Proof** As in the proof of Theorem 13.17, we let \( t \in S \) be a generator of the principal ideal \( S_Q \) and so \( t \in S \cap S_Q \). If \( \sigma \in V_i \), then \( \sigma(t) = t + x_\sigma t^{i+1} \), where \( x_\sigma \in S_Q \) (Proposition 13.16).

From Corollary 12.10, there is an isomorphism \( \phi \) from \( S_Q/S_QQ \) onto \( S/Q \). Noting \( \tilde{x}_\sigma \) the image \( \phi(x_\sigma + S_QQ) \), we obtain a mapping \( \theta_i \) from \( V_i \) into \( S/Q \) defined by

\[
\theta_i(\sigma) = \tilde{x}_\sigma.
\]

We claim that \( \theta_i \) is a homomorphism into the additive group of \( S/Q \). If \( \sigma, \tau \in V_i \), then

\[
\sigma\tau(t) = \sigma(t + x_\tau t^{i+1}) = \sigma(t) + \sigma(x_\tau)\sigma(t^{i+1}).
\]

If \( x = \frac{r}{u} \in S_Q \) and \( \sigma \in V_i \), then there exist \( q, q' \in Q^{i+1} \) such that

\[
\sigma(x) = \frac{\sigma(r)}{\sigma(u)} = \frac{r + q'}{u + q'} = \frac{r - rq' - uq}{u(u + q')} = x + q_1,
\]

with \( q_1 \in S_Q Q^{i+1} \). Thus

\[
\sigma\tau(t) = t + x_\sigma t^{i+1} + (x_\tau + vt^{i+1})(t + x_\sigma t^{i+1})^{i+1}.
\]

However,

\[
(t + x_\sigma t^{i+1})^{i+1} = t^{i+1} + x_\sigma(i + 1)t^{2i+1} + \text{expressions in higher powers of } t,
\]

with \( 2i + 1 > i + 1 \), because \( i \geq 1 \). Hence

\[
\sigma\tau(t) = t + (x_\sigma + x_\tau + v't)t^{i+1},
\]

where \( v, v' \in S_Q \). It follows that

\[
\theta_i(\sigma\tau) = x_\sigma + x_\tau + v't = \tilde{x}_\sigma + \tilde{x}_\tau = \tilde{x}_\sigma + \tilde{x}_\tau = \theta_i(\sigma) + \theta_i(\tau).
\]

We have shown that \( \theta_i \) is a homomorphism from \( V_i \) into the additive group of \( S/Q \).

Our next task is to consider the kernel of \( \theta_i \). If \( \sigma \in V_{i+1} \), then, for some \( v \in S_Q \),

\[
\sigma(t) - t \in S_Q Q^{i+2} \Rightarrow \sigma(t) = t + vt^{i+2} = t + (vt)t^{i+1}
\]

and so

\[
\theta_i(\sigma) = vt = 0.
\]
So we have $V_{i+1} \subset \text{Ker} \theta_i$. Now suppose that $\theta_i(\sigma) = \bar 0$. Then $\bar x_\sigma = 0$, which implies that
\[ \sigma(t) = t + (vt)t^{i+1} = t + vt^{i+2}, \]
with $v \in S_Q$. Therefore $\sigma \in V_{i+1}$ and it follows that $\text{Ker} \theta_i = V_{i+1}$. Therefore the quotient group $V_i/V_{i+1}$ is isomorphic to a subgroup of the additive group of $S/Q$. We have seen in the proof of Theorem 13.17 that $|S/Q| = p^n$, where $Q \cap \mathbb{Z} = \mathbb{Z}p$ and $n$ is a positive integer, so $|V_i/V_{i+1}| = p^m$, where $m \leq n$. Therefore the order of an element in $V_i/V_{i+1}$ is a power of $p$.

**Exercise 13.6** In the proof of the preceding theorem we have used a particular generator $t \in S$ of the principal ideal $S\mathbb{Q}$ to construct the homomorphism $\theta_i$, which in turn gives us a monomorphism $\bar \theta_i$ of $V_i/V_{i+1}$ into $S/Q$. Suppose that we take another generator $t' \in S$ of $S\mathbb{Q}$ and so obtain another monomorphism of $\bar \theta'_i$ of $V_i/V_{i+1}$ into $S/Q$. What can we say of the relation between $\bar \theta_i$ and $\bar \theta'_i$?

We recall the definition of a solvable group. A normal series of a finite group $G$, with identity $e$, is a chain of subgroups
\[ G = G_0 \supset G_1 \supset \cdots \supset G_n = \{e\}, \]
where the subgroup $G_{i+1}$ is normal in $G_i$, for all $i$. If a finite group $G$ has such a series and all the quotient groups $G_i/G_{i+1}$ are abelian, then we say that $G$ is a solvable group.

**Proposition 13.17** The inertia and decomposition groups are solvable.

**Proof** The series
\[ D \supset E \supset V_1 \supset \cdots \supset V_m = \{\text{id}_D\} \]
is a normal series, because $E, V_1, \ldots, V_m$ are normal in $D$. In Section 13.6 we saw that $D/E$ is cyclic and from Theorems 13.17 and 13.18 above, for $i \geq 0$, $V_i/V_{i+1}$ is a subgroup of an abelian group, hence abelian. It follows that $E$ and $D$ are solvable groups.

Here are two further results concerning the first ramification group $V_1$.

**Proposition 13.18** We have

- a. The cardinal of $V_1$ is a power of $p$, hence $V_1$ is a $p$-group: $|V_1| = p^k$, where $k \geq 0$;

- b. If $e$ is the ramification index $e(Q|P)$, then $e = mp^k$, where $p \not| m$ and $m = |E/V_1|$.

**Proof a.** As $V_m$ is reduced to the identity, we may write
\[ |V_1| = |V_1/V_m| \cdot |V_1/V_2| \cdot |V_2/V_3| \cdots |V_{m-1}/V_m|. \]
As all the factors on the right hand side are powers of $p$, so is $|V_1|$.  

b. From Proposition 13.11, $e = [L : L^E]$. In addition, from Theorem 6.6, $[L : L^E] = |E|$, which in turn is equal to $|V_1||E/V_1|$. Using part a. we obtain $e = p^km$, and $p \not| m$, by Theorem 13.17. □

We have seen that $V_1$ and $E$ are normal subgroups of $D$. As $E$ is contained in $D$, $V_1$ is also normal subgroup of $E$ and so the cosets of $V_1$ in $E$ form a group, the quotient group $E/V_1$. We may define an action of $D$ on $E/V_1$ by conjugation: for $\sigma \in D$ and $\tau V_1 \in E/V_1$, we set
\[ \sigma \cdot \tau V_1 = \sigma (\tau V_1) \sigma^{-1} = (\tau \sigma^{-1}) V_1. \]
(It is simple to check that this action is well-defined, i.e., if \( \tau V_1 = \tau V_1 \), then \( \sigma \cdot \tau V_1 = \sigma \cdot \tau V_1 \). From the group action we obtain, for each \( \sigma \in D \), a bijection \( \tilde{\sigma} \) of \( E/V_1 \) defined by
\[
\tilde{\sigma}(\tau V_1) = \sigma \cdot \tau V_1 = \sigma(\tau V_1)\sigma^{-1}.
\]

We may also define an action of \( D \) on \( S/Q \): for \( \sigma \in D \) and \( s + Q \in S/Q \), we set
\[
\sigma \cdot (s + Q) = \sigma(s) + Q.
\]

(There is no difficulty in seeing that this action also is well-defined.) From this second group action we obtain, for each \( \sigma \in D \), a bijection \( \tilde{\sigma} \) of \( S/Q \) defined as follows:
\[
\tilde{\sigma}(s + Q) = \sigma \cdot (s + Q) = \sigma(s) + Q.
\]

In Section 13.6 we saw that the bijections \( \tilde{\sigma} \) belong to the Galois group \( Gal(S/Q, R/P) = \hat{G} \) and that the corresponding mapping \( \psi : \sigma \mapsto \tilde{\sigma} \) is an epimorphism. Moreover, \( \hat{G} \) is a cyclic group generated by the Frobenius automorphism: \( Fr : \hat{x} \mapsto \hat{x}^q \), where \( q = |R/P| \). The following result links the bijections \( \tilde{\sigma} \) and \( \hat{\sigma} \).

**Proposition 13.19** If \( \sigma \in D \) is such that \( \psi(\sigma) = \hat{\sigma} \) is the Frobenius automorphism, then
\[
\tilde{\sigma}(\tau V_1) = \tau^q V_1,
\]
for all cosets \( \tau V_1 \in E/V_1 \).

**Proof** First we fix a generator \( t \) of the ideal \( S_QQ, \) i.e., \( S_QQ = SQt \). As \( \tilde{\sigma}(\tau V_1) = \tau \sigma \sigma^{-1} \), we have
\[
\tilde{\sigma}(\tau V_1) = \tau^q V_1 \iff \tau \sigma \sigma^{-1} \tau^q \in V_1 \iff \tau \sigma \sigma^{-1} \tau^q(t) \equiv t \ (mod \ S_QQ^2).
\]

We now sum up some basic facts which we will need further on in the proof:

- For all \( \sigma \in D \), there exists \( x_\sigma \in S_Q \) such that \( \sigma(t) = x_\sigma t \) and
  \[
  \sigma(x_{\sigma^{-1}})x_\sigma = 1.
  \]
  (This result is established in the proof of Theorem 13.17.)
- If \( \sigma \in D \) and \( x \in S_Q \), then
  \[
  \sigma(x) \in S_Q.
  \]
  Indeed, \( x = \frac{r}{u} \in S_Q \) can be considered an element of \( L \), thus \( \sigma(x) = \frac{\sigma(r)}{\sigma(u)} \), because \( \sigma(\frac{r}{u})\sigma(u) = \sigma(\frac{r}{u})u = \sigma(r) \). If \( \sigma(u) \in Q \), then \( u = \sigma^{-1}(\sigma(u)) \in \sigma^{-1}(Q) = Q \), because \( \sigma^{-1} \in D \), a contradiction. Therefore \( \sigma(u) \notin Q \) and so \( \frac{\sigma(r)}{\sigma(u)} \in S_Q \).
- If \( \tau \in E \) and \( x \in S_Q \), then
  \[
  \tau(x) \equiv x \ (mod \ S_QQ).
  \]
  Since \( \tau : L \longrightarrow L \) satisfies the condition \( \tau(\alpha) \equiv \alpha \ (mod \ Q) \), for all \( \alpha \in S \), we have \( \tau(x) \equiv x \ (mod \ S_QQ) \), for all \( x \in S_Q \), because
  \[
  x = \frac{r}{u} \in S_Q \subset L \implies \tau(x) = \frac{\tau(r)}{\tau(u)} = \frac{r + q}{u + q'} = \frac{r - rq' - uq}{u(u + q')} = x + q_1,
  \]
  with \( q_1 \in S_QQ \).

198
With these rules in mind we aim to show that
\[ \sigma^{-1} \sigma^{-1} \tau^q(t) \equiv t \pmod{S_Q Q^2}. \]

To begin with, we establish that for \(1 \leq i \leq q\) we have
\[ \tau^i(t) \equiv x_i^2 t \pmod{S_Q Q^2}. \]

For \(i = 1\), the result is clear, because \(\tau(t) = x_\tau t\). Next we consider the case \(i = 2\). First,
\[ \tau(t) = x_\tau t \implies \tau^2(t) = \tau(x_\tau) \tau(t) = \tau(x_\tau) x_\tau t. \]
As \(\tau \in E\), there exists \(v \in S_Q\) such that \(\tau(x_\tau) = x_\tau + vt\), hence
\[ \tau^2(t) = (x_\tau + vt)x_\tau t = x_\tau^2 t + vxt^2 = x_\tau^2 t + v_1 t^2. \]
As \(v_1 \in S_Q\), we have
\[ \tau^2(t) \equiv x_\tau^2 t \pmod{S_Q Q^2}. \]

Our next step is to consider the case \(i = 3\). We have
\[ \tau^3(t) = \tau(\tau^2(t)) = \tau(x_\tau^2 t + v_1 t) \]
\[ = \tau(x_\tau^2 \tau(t) + \tau(v_1) \tau(t))^2 \]
\[ = (x_\tau + vt) x_\tau t + \tau(v_1)(x_\tau t)^2 \]
\[ = x_\tau^3 t + v_2 t^2, \]
where \(v_2 \in S_Q\). Hence
\[ \tau^3(t) \equiv x_\tau^3 t \pmod{S_Q Q^2}. \]

Continuing in the same way we obtain
\[ \tau^i(t) \equiv x_i^2 t \pmod{S_Q Q^2}, \]
for \(1 \leq i \leq q\) and, in particular for \(i = q\). Therefore there exists \(w \in S_Q\) such that
\[ \tau^q(t) = x_\tau^q t + wt^2. \]

We now consider the expression \(\sigma^{-1} \sigma^{-1} \tau^q\). First,
\[ \sigma^{-1}(\tau^q(t)) = \sigma^{-1}(x_\tau^q t + wt^2) \]
\[ = \sigma^{-1}(x_\tau^q t) x_{\sigma^{-1}} t + \sigma^{-1}(w) \sigma^{-1}(t)^2 \]
\[ = \sigma^{-1}(x_\tau^q t) x_{\sigma^{-1}} t + \sigma^{-1}(w) x_{\sigma^{-1}}^2 t^2 \]
\[ = \sigma^{-1}(x_\tau^q t) x_{\sigma^{-1}} t + w_1 t^2, \]
where \(w_1 \in S_Q\). Thus
\[ \sigma^{-1}(\tau^q(t)) \equiv \sigma^{-1}(x_\tau^q t) x_{\sigma^{-1}} t \pmod{S_Q Q^2} \]
and so
\[ \tau^{-1} \sigma^{-1} \tau^q(t) \equiv \tau^{-1}(\sigma^{-1}(x_\tau^q t) x_{\sigma^{-1}} t) \pmod{S_Q Q^2} \]
\[ \equiv \sigma^{-1}(x_\tau^q) x_{\sigma^{-1}} x_{\tau^{-1}} t \pmod{S_Q Q^2}, \]

199
because \( \tau^{-1} \in E \) implies that

\[
\tau^{-1}(\sigma^{-1}(x^q_{\sigma-1})) \equiv \sigma^{-1}(x^q_{\sigma-1}) (\text{mod } S_Q).
\]

Thus

\[
\sigma \tau^{-1} \sigma^{-1} \tau^q(t) \equiv x^q_{\sigma}(x_{\sigma-1}) \sigma(x_{\sigma-1}) t (\text{mod } S_Q)
\]

\[
\equiv x^q_{\sigma}(x_{\sigma-1}) t (\text{mod } S_Q^2),
\]

because \( \sigma(x_{\sigma-1}) x_{\sigma} = 1 \).

Our next step is to find useful expressions for \( x^q_{\sigma} \) and \( \sigma(x_{\sigma-1}) \). Firstly, as \( \tau^{-1} \in E \), we have

\[
x_{\tau} \equiv \tau^{-1}(x_{\tau}) (\text{mod } S_Q) \implies x^q_{\tau} \equiv \tau^{-1}(x^q_{\tau}) (\text{mod } S_Q).
\]

Secondly, we consider \( \sigma(x_{\sigma-1}) \). Since \( \sigma(\alpha) \equiv \alpha^q (\text{mod } Q) \), for all \( \alpha \in S \), because \( \tilde{\alpha} \) is the Frobenius automorphism, we have \( \sigma(x) \equiv x^q (\text{mod } S_Q) \), for all \( x \in S \): For \( x = \frac{z}{u} \in S \subset L \), we have

\[
\sigma(x) = \sigma(u) = \frac{r^q + q_1}{u^q + q_2} = \frac{r^q - r^q q_2 - u^q q_1}{u^q(u^q + q_2)} \equiv \frac{r^q}{u^q} (\text{mod } S_Q).
\]

Hence

\[
\sigma(x_{\sigma-1}) \equiv x^q_{\sigma^{-1}} (\text{mod } S_Q).
\]

Using these two expressions, we have

\[
\sigma \tau^{-1} \sigma^{-1} \tau^q(t) \equiv x^q_{\sigma}(x_{\sigma-1}) t \equiv \tau^{-1}(x^q_{\sigma}) x^q_{\sigma^{-1}} t (\text{mod } S_Q^2).
\]

As \( \tau^{-1}(x_{\tau}) x_{\tau-1} = 1 \), we finally obtain

\[
\sigma \tau^{-1} \sigma^{-1} \tau^q(t) \equiv t (\text{mod } S_Q^2),
\]

and the result follows.

\[\square\]

**Corollary 13.9** If the decomposition group \( D \) is abelian, then then \( |E/V_1| \) divides \( q - 1 \).

**Proof** If \( D \) is abelian, then the action of \( D \) on \( E/V_1 \) is trivial, i.e., \( \sigma \cdot \tau V_1 = \tau V_1 \), for all \( \sigma \in D \) and cosets \( \tau V_1 \in E/V_1 \). It follows that \( \tilde{\sigma} \) is the identity for every \( \sigma \in D \). If \( \sigma \) is such that its image under the mapping \( \psi \) is the Frobenius automorphism, then from Proposition 13.19 \( \sigma(\tau V_1) = \tau^q V_1 \). Thus we have \( \tau V_1 = \tau^q V_1 \), or \( \tau^{-1}(\tau V_1) = \tau V_1 \). Hence the order of \( \tau V_1 \) divides \( q - 1 \). However, \( E/V_1 \) is cyclic, so if \( \tau V_1 \) is a generator of \( E/V_1 \), then its order is the cardinal of the group, hence the result.

\[\square\]

**Remark** In the proof of Theorem 13.17 we showed that \( |E/V_1| \) divides \( q' - 1 \), where \( q' = |S/Q| \). On the other hand, in Corollary 13.9 we show that \( |E/V_1| \) divides \( q - 1 \), where \( q = |R/Q| \). As \( q - 1 \) divides \( q' - 1 \), when \( D \) is abelian we obtain a stronger result.

200
Chapter 14

Number fields and lattices

Before reading this chapter we advise the reader unfamiliar with lattices in euclidian space to read our appendix on the subject. There we have brought together the basic notions on the subject and, in particular, we state and prove Minkowski’s convex body theorem.

14.1 Number rings as lattices

We consider a number field \( K \), such that \([K : \mathbb{Q}] = n\), with associated number ring \( R \). There are \( n \) monomorphisms of \( K \) into \( \mathbb{C} \) which fix \( \mathbb{Q} \). (If \( K \) is a normal extension of \( \mathbb{Q} \), then the monomorphisms are automorphisms of \( K \) and so form the Galois group \( \text{Gal}(K/\mathbb{Q}) \).) Let \( \sigma_1, \ldots, \sigma_r \) be the monomorphisms with image in \( R \). The others occur as pairs of complex conjugates, which we write \( \tau_1, \overline{\tau}_1, \ldots, \tau_s, \overline{\tau}_s \); clearly, \( n = r + 2s \).

We obtain a mapping \( \phi : K \rightarrow \mathbb{R}^n \) by setting

\[
\phi(\alpha) = (\sigma_1(\alpha), \ldots, \sigma_r(\alpha), \text{Re} \tau_1(\alpha), \text{Im} \tau_1(\alpha), \ldots, \text{Re} \tau_s(\alpha), \text{Im} \tau_s(\alpha)),
\]

for all \( \alpha \in K \). This mapping is a monomorphism from the additive group of \( K \) into the additive group of \( \mathbb{R}^n \). The image of \( R \), which we note \( \Lambda_R \), is a subgroup of the additive group of \( \mathbb{R}^n \). We claim that \( \Lambda_R \) is a lattice. To see this, let \((\alpha_1, \ldots, \alpha_n)\) be an integral basis of \( R \). Clearly

\[
\Lambda_R = \{ v \in \mathbb{R}^n : v = \sum_{i=1}^{n} a_i \phi(\alpha_i), a_i \in \mathbb{Z} \}.
\]

In order to show that \( A = \{ \phi(\alpha_1), \ldots, \phi(\alpha_n) \} \) is an independant set in \( \mathbb{R}^n \) we consider the determinant \( D \) of the matrix having these elements as rows. Applying appropriate column operations we obtain that \( D \) is the product of \((-2i)^{-s}\) and the determinant \( D' \) of the matrix with rows

\[
\sigma_1(\alpha_i) \ldots \sigma_r(\alpha_i) \tau_1(\alpha_i) \overline{\tau}_1(\alpha_i) \ldots \tau_s(\alpha_i) \overline{\tau}_s(\alpha_i)
\]

However,

\[
D'^2 = \text{disc}(R) \neq 0,
\]

since any integral basis of \( R \) is a basis of the vector space \( K \) over \( \mathbb{Q} \) and Proposition 10.8 holds. Thus \( A \) is an independant set. It follows that \( \Lambda_R \) is a lattice.

We recall that the determinant of a lattice \( \Lambda \) is the volume of a parallelepiped formed by the vectors of any basis \((u_i)_{i=1}^n\). This volume is the absolute value of the determinant of the matrix
$U$ having these vectors as columns. Hence $\det \Lambda_R = |D|$. Now,
\[
D = (-2i)^s D' \implies D^2 = (-1)^s 2^{-2s} D'^2,
\]
therefore
\[
\det \Lambda_R = |D| = 2^{-s} \sqrt{|\text{disc}(R)|}.
\]
If $I$ is a nonzero ideal of $R$, then we claim that $\Lambda_I = \phi(I)$ is a sublattice of $\Lambda_R$. To see this, we notice that $I$ is a free abelian group of rank $n$ and hence has a basis $(\beta_1, \ldots, \beta_n)$. The set $B = \{\phi(\beta_1), \ldots, \phi(\beta_n)\}$ generates $\phi(I)$ over $\mathbb{Z}$ and is independent, hence $\Lambda_I$ is a sublattice of $\Lambda_R$. Also, the index of $\Lambda_I$ in $\Lambda_R$ is that of $I$ in $R$, since the mapping
\[
\pi : R/I \longrightarrow \Lambda_R/\Lambda_I, r + I \longmapsto \phi(r) + \Lambda_I
\]
is a bijection. Therefore, using Theorem G.5, we have
\[
\|I\| = |R/I| = \frac{\det \Lambda_I}{\det \Lambda_R} \implies \det \Lambda_I = \det \Lambda_R \|I\| = 2^{-s} \sqrt{|\text{disc}(R)|}\|I\|.
\]

14.2 Some calculus

In this section we consider a particular subset of $\mathbb{R}^n$, with $n \geq 1$, which we will use further on. We devote a section to the calculation of its volume. We suppose that $n = r + 2s$ and set
\[
A = \{x \in \mathbb{R}^n : |x_1| + \cdots + |x_r| + 2 \left( \sqrt{x_{r+1}^2 + x_{r+2}^2} + \cdots + \sqrt{x_{n-1}^2 + x_n^2} \right) \leq n \}.
\]
Before considering the volume of the set $A$, we observe certain of its properties. For $x = (x_1, \ldots, x_r, x_{r+1}, \ldots, x_{r+2s}) \in \mathbb{R}^n$, we set
\[
S(x) = x_1 \cdots x_r (x_{r+1}^2 + x_{r+2}^2) \cdots (x_{n-1}^2 + x_n^2).
\]

**Proposition 14.1** The set $A$ is a convex, compact, centrally symmetric subset of $\mathbb{R}^n$, such that, for all $x \in A$,
\[
|S(x)| \leq 1.
\]

**Proof** $A$ is clearly convex, compact and centrally symmetric. The arithmetic mean of the numbers
\[
|x_1|, \ldots, |x_r|, \sqrt{x_{r+1}^2 + x_{r+2}^2}, \sqrt{x_{r+1}^2 + x_{r+2}^2}, \ldots, \sqrt{x_{n-1}^2 + x_n^2}, \sqrt{x_{n-1}^2 + x_n^2}
\]
is at most 1 and their geometric mean, which is $\sqrt[n]{|S(x)|}$ is bounded above by the arithmetic mean, therefore $|S(x)| \leq 1$. \qed

We now turn to the calculation of the volume of $A$.

**Theorem 14.1** We have
\[
\text{vol } A = \frac{n^n}{n!} 2^s \left( \frac{\pi}{2} \right)^s.
\]
PROOF We consider the volume \( v_{r,s}(t) \) of the subset of \( \mathbb{R}^{n+2s} \)
\[
A_{r,s}(t) = \{ x \in \mathbb{R}^n : |x_1| + \cdots + |x_r| + 2 \left( \sqrt{x_{r+1}^2 + x_{r+2}^2} + \cdots + \sqrt{x_{n-1}^2 + x_n^2} \right) \leq t \}.
\]
As \( A_{r,s}(t) = tA_{r,s}(1) \), we have
\[
v_{r,s}(t) = t^{n+2s} v_{r,s}(1). \tag{14.1}
\]
Given that \( \text{vol} A = v_{r,s}(r + 2s) \), it is sufficient to show that
\[
v_{r,s}(1) = \frac{1}{(r + 2s)!} 2^r \left( \frac{\pi}{2} \right)^s. \tag{14.2}
\]
We first consider the case where \( r = 0 \); this implies that \( s \geq 1 \), because \( n \neq 0 \). For \( s = 1 \) we have
\[
v_{0,s}(1) = \int \int_{x^2+y^2 \leq \frac{1}{4}} 1 \, dx \, dy = \frac{\pi}{4}.
\]
We now suppose that \( s > 1 \) and aim to find a relation between \( v_{0,s}(1) \) and \( v_{0,s-1}(1) \). To simplify the notation we let \( f \) be the characteristic function of \( A_{0,s}(1) \). \( f \) is a function in the variables \( x_1, \ldots, x_{2s} \). Let us set \( u = (x_1, \ldots, x_{2s-2} \) and \( v = (x_{2s-1}, x_{2s}) \). If \( f_v \) is the function in \( u \) obtained by fixing \( v \) and we set
\[
\phi(v) = \int f_v(u) \, du,
\]
then, by Fubini’s theorem (see for example [20]), we have
\[
\int \phi(v) \, dv = \int \int f(u,v) \, dudv.
\]
However, \( f_v(u) \) is the characteristic function of the set
\[
A_v = \{ (x_1, \ldots, x_{2s-2}) \in \mathbb{R}^{2s-2} : 2 \left( \sqrt{x_1^2 + x_2^2 + \cdots + \sqrt{x_{2s-3}^2 + x_{2s-2}^2}} \right) \leq 1 - 2 \sqrt{x_{2s-1}^2 + x_{2s}^2} \}.
\]
From equation (14.1),
\[
\int f_v(u)du = \left( 1 - 2 \sqrt{x_{2s-1}^2 + x_{2s}^2} \right)^{2s-2} v_{0,s-1}(1)
\]
and so, writing \( f(u,v) \) for \( f_v(u) \),
\[
\int f(u,v) \, dudv = v_{0,s}(1) = \int \int_{x^2+y^2 \leq \frac{1}{4}} v_{0,s-1}(1) \left( 1 - 2 \sqrt{x^2 + y^2} \right)^{2s-2} \, dx \, dy = v_{0,s-1}(1) \int \int_{x^2+y^2 \leq \frac{1}{4}} \left( 1 - 2 \sqrt{x^2 + y^2} \right) \, dx \, dy.
\]
Using polar coordinates we obtain
\[
\int \int_{x^2+y^2 \leq \frac{1}{4}} \left( 1 - 2 \sqrt{x^2 + y^2} \right)^{2s-2} \, dx \, dy = \int_0^{2\pi} \int_0^{\frac{1}{2}} (1 - 2\rho)^{2s-2} \rho \, d\rho \, d\theta = 2\pi \int_0^{\frac{1}{2}} (1 - 2\rho)^{2s-2} \rho \, d\rho = \frac{\pi}{2} \int_0^{1} u^{2s-2} (1 - u) \, du = \frac{\pi}{2} \left( \frac{1}{2s - 1} - \frac{1}{2s} \right) = \frac{\pi}{2} \frac{1}{2s(2s - 1)}
\]
203
and hence the recurrence relation
\[ v_{0,s}(1) = v_{0,s-1}(1) \frac{\pi}{2} \frac{1}{2s(2s-1)}. \]

With an induction argument we find that
\[ v_{0,s}(1) = \left( \frac{\pi}{2} \right)^s \frac{1}{(2s)!}. \]

We now consider the case where \( r > 0 \) and \( s \geq 1 \). Let \( g \) be the characteristic function of \( A_{r,s}(1) \). \( g \) is a function in the variables \( x_1, \ldots, x_{2s} \). Let us set \( u = (x_1, \ldots, x_{r-1}, x_{r+1}, \ldots, x_{2s}) \)
and \( v = x_r \). If \( g_v \) is the function in \( u \) obtained by fixing \( v \) and we set
\[ \psi(v) = \int g_v(u) \ du, \]
then, by Fubini’s theorem, we have
\[ \int \psi(v) \ dv = \int \int g(u, v) \ dudv. \]

However, \( g_v(u) \) is the characteristic function of the set
\[ B_v = \{ (x_1, \ldots, x_{r-1}, x_{r+1}, \ldots, x_{2s}) \in \mathbb{R}^{r-1+2s} : |x_1| + \cdots + |x_{r-1}| \]
\[ + 2 \left( \sqrt{x_{r+1}^2 + x_{r+2}^2} + \cdots + \sqrt{x_{2s-1}^2 + x_{2s}^2} \right) \leq 1 - |x_r| \} \]

From equation (14.1), we obtain
\[ \int g_v(u) \ du = (1 - |x_r|)^{r-1+2s} v_{r-1,s}(1) \]
and so, writing \( g(u, v) \) for \( g_v(u) \),
\[ \int g(u, v) \ dudv = v_{r,s}(1) = \int_{-1}^1 (1 - |x|)^{r-1+2s} v_{r-1,s}(1) \ dx \]
\[ = 2v_{r-1,s}(1) \int_0^1 (1 - x)^{r-1+2s} \ dx \]
\[ = \frac{2}{r+2s} v_{r-1,s}(1). \]

Using this recurrence relation and the value of \( v_{0,s}(1) \), which we have already determined, we obtain the expression for \( v_{r,s}(1) \) in equation (14.2), namely
\[ v_{r,s}(1) = \frac{1}{(r+2s)!} \left( \frac{\pi}{2} \right)^s. \]

There is one case we have not considered, namely that where \( r > 0 \) and \( s = 0 \). However, this is not difficult. As above, for \( r > 1 \) we may obtain the recurrence relation
\[ v_{r,0}(1) = \frac{2}{r} v_{r-1,0}(1). \]
This, together with the fact that $v_{1,0}(1) = 2$, enables us to establish by induction that

$$v_{r,0}(1) = \frac{2^r}{r!}$$

and hence

$$\text{vol } A = \frac{n^n}{n!} 2^n,$$

as desired. This finishes the proof. \hfill \square

In the next section we will use the results we have considered here to prove certain important properties of number rings.

### 14.3 The ideal class group of a number ring

We now return to number rings. As usual, let $K$ be a number field with number ring $R$. We recall that in the first section of this chapter we defined a monomorphism $\phi : K \rightarrow \mathbb{R}^n$, where $n$ is the degree of the extension of $K$ over $\mathbb{Q}$, such that the image of $R$ is a lattice $\Lambda_R$. We begin with a property of general lattices.

**Theorem 14.2** If $A$ is a compact, convex, centrally symmetric subset of $\mathbb{R}^n$, with $\text{vol } A > 0$, satisfying the property

$$a \in A \implies |S(a)| \leq 1,$$

then every lattice $\Lambda \subset \mathbb{R}^n$ contains a nonzero point $x$ such that

$$|S(x)| \leq \frac{2^n}{\text{vol } A} \det \Lambda.$$

**Proof** We use Minkowski’s convex body theorem (Theorem G.4). First we set $B = tA$, where $t > 0$ and

$$t^n = \frac{2^n}{\text{vol } A} \det \Lambda.$$

Then

$$\text{vol } B = t^n \text{vol } A = 2^n \det \Lambda.$$

From Minkowski’s theorem, $B$ contains a nonzero lattice point $x$. As $\frac{x}{t} \in A$, we have

$$|S(x)| = t^n |S(\frac{x}{t})| \leq \frac{2^n}{\text{vol } A} \det \Lambda.$$

This ends the proof. \hfill \square

Suppose now that we can write $n = r + 2s$ and we take $A$ to be the corresponding set defined in the previous section, then

$$\text{vol } A = \frac{n^n}{n!} 2^r \left( \frac{\pi}{2} \right)^s$$

and so we obtain

**Corollary 14.1** Every lattice $\Lambda \subset \mathbb{R}^n$ contains a nonzero point $x$ such that

$$|S(x)| \leq \frac{n!}{n^n} \left( \frac{8}{\pi} \right)^s \det \Lambda.$$
**Remark** We emphasize that the set $A$ and the application $S$ depend on the values of $r$ and $s$.

We now return to the number field $K$.

**Lemma 14.1** If $\alpha \in K$, then for $x = \phi(\alpha)$, we have

$$S(x) = N_{K/Q}(\alpha).$$

**Proof** Since

$$\phi(\alpha) = (\sigma_1(\alpha), \ldots, \sigma_r(\alpha), \text{Re} \tau_1(\alpha), \text{Im} \tau_1(\alpha), \ldots \text{Re} \tau_s(\alpha), \text{Im} \tau_s(\alpha)),$$

then, by Proposition 10.2,

$$S(\phi(\alpha)) = \sigma_1(\alpha) \cdots \sigma_r(\alpha) \tau_1(\alpha) \bar{\tau}_1(\alpha) \cdots \tau_s(\alpha) \bar{\tau}_s(\alpha) = N_{K/Q}(\alpha).$$

This ends the proof. □

**Theorem 14.3** A nonzero ideal $I$ in $R$, the number ring of $K$, contains a nonzero element $\alpha$ such that

$$|N_{K/Q}(\alpha)| \leq \frac{n!}{n^n} \left(\frac{4}{\pi}\right)^{s} \sqrt{|\text{disc}(R)|} \|I\|.$$ 

**Proof** Corresponding to the ideal $I$ is the lattice $\Lambda_I = \phi(I)$. From Lemma 14.1, there exists a nonzero lattice point $x$ such that

$$|S(x)| \leq \frac{n!}{n^n} \left(\frac{8}{\pi}\right)^{s} \det \Lambda_I.$$ 

There exists $\alpha$ nonzero in $I$ such that $x = \phi(\alpha)$ and, from Lemma 14.1, $S(x) = N_{K/Q}(\alpha)$. In addition, in Section 14.1 it is established that $\det \Lambda_I = \frac{1}{\pi} \sqrt{|\text{disc}(R)|} \|I\|$, therefore

$$|N_{K/Q}(\alpha)| \leq \frac{n!}{n^n} \left(\frac{4}{\pi}\right)^{s} \sqrt{|\text{disc}(R)|} \|I\|,$$

as required. □

From this theorem we may deduce two important results, namely

- the number of ideal classes in a number ring is finite;
- for any number field $K \neq \mathbb{Q}$, there is a prime number $p$ which is ramified in the number ring $R$ of $K$.

Let us consider the first question. We set $\lambda = \frac{n!}{n^n} \left(\frac{4}{\pi}\right)^{s} \sqrt{|\text{disc}(R)|}$. (The number $\lambda$ is called a Minkowski bound.)

**Proposition 14.2** Every ideal class of $R$ contains an ideal $J$ such that $\|J\| \leq \lambda$.

**Proof** Let $C$ be an ideal class. As the ideal classes form a group, there exists an ideal class $C^{-1}$. Let $I$ be an ideal in the class $C^{-1}$. From Theorem 14.3, there exists a nonzero $\alpha \in I$ such that $|N_{K/Q}(\alpha)| \leq \lambda \|I\|$. $I$ contains the principal ideal $(\alpha)$, which implies that $I$ divides $(\alpha)$, i.e.,

$$206$$
there exists an ideal \( J \) such that \( IJ = (\alpha) \). As \((\alpha)\) is an element of identity class, \( J \) lies in the class \( C \). Therefore, using Theorems 13.2 and 13.4, we have
\[
|N_{K/Q}(\alpha)| = \| (\alpha) \| = \| I \| \| J \|,
\]
which implies that
\[
\| J \| = \frac{|N_{K/Q}(\alpha)|}{\| I \|} \leq \frac{\| I \| \lambda}{\| I \|} = \lambda,
\]
as required.

We may now handle the first question.

**Theorem 14.4** If \( R \) is a number ring, then there is only a finite number of ideal classes in \( R \).

**Proof** We claim that there is only a finite number of nonzero ideals \( J \) such that \( \| J \| \leq \lambda \). Let \( J \) be such an ideal. If the decomposition of \( J \) into prime ideals is
\[
J = P_1^{n_1} \cdots P_s^{n_s},
\]
then, by Theorem 13.2,
\[
\| P_1 \|^n_1 \cdots \| P_s \|^n_s \leq \lambda.
\]
Each prime ideal \( P_i \) lies over a unique prime number \( p_i \) and \( \| P_i \| = p_i^{u_i} \), for some \( u_i \in \mathbb{N}^* \). Hence
\[
\| P_i \|^n_i = p_i^{u_i n_i} \leq \lambda \implies p_i \leq \lambda.
\]
There is only a finite number of prime numbers \( p \) such that \( p \leq \lambda \), thus in the decomposition of \( J \) there can only be prime ideals lying over a finite number of prime numbers. However, from Theorem 13.1, we know that there is only a finite number of prime ideals lying over a given prime number, so in the decomposition of \( J \) there can only be members of a certain finite set of prime ideals. If \( P \) is one such prime and \( P^m \) is in the decomposition of \( J \), then \( \| P \|^m \leq \lambda \), so there can only be finite number of powers of \( P \) in the decomposition of ideals \( J \). It now follows that there is only a finite number of nonzero ideals \( J \) such that \( \| J \| \leq \lambda \), as claimed.

As any class contains a nonzero ideal \( J \) such that \( \| J \| \leq \lambda \), there can only be a finite number of ideal classes.

**Remark** To prove Theorem 14.4 we only need to know that there is some constant \( \lambda \) such that every ideal class of \( R \) contains an ideal \( J \) satisfying the inequality \( \| J \| \leq \lambda \). There exists at least one other such constant, namely
\[
H_K = \prod_{i=1}^n \sum_{j=1}^n |\sigma_i(b_j)|,
\]
where \( \mathcal{B} = \{ b_1, \ldots, b_n \} \) is an integral basis of \( O_K \) and \( \sigma_1, \ldots, \sigma_n \) are the embeddings of \( K \) in \( \mathbb{C} \) (see [15]). This constant is known as Hurwitz’s constant, hence the notation, although it is not certain that Hurwitz was the first to find it. It has the disadvantage of being dependant on the basis chosen and is also in general larger than Minkowski’s constant. We will see further on that the bounding constant can be used in determining the class group and it is important that this be as small as possible.

**Definition** The cardinal of the class group of a number ring \( O_K \) is referred to as the class number of \( K \). In general we write \( h(K) \) (or just \( h \)) for the class number.

We now turn to the second question.
**Theorem 14.5** For any number field $K \neq \mathbb{Q}$, there is a prime number $p$ which is ramified in the number ring $R$ of $K$.

**Proof** From Proposition 14.2 we know that there is a nonzero ideal $J$ such that

$$||J|| \leq \lambda = \frac{n!}{n^n} \left(\frac{4}{\pi}\right)^s \sqrt{|\text{disc}(R)|} \implies \sqrt{|\text{disc}(R)|} \geq \frac{n^n}{n!} \left(\frac{\pi}{4}\right)^{\frac{n-s}{2}},$$

because $n = r + 2s$. As $\frac{s}{4} < 1$, we have

$$\sqrt{|\text{disc}(R)|} \geq \frac{n^n}{n!} \left(\frac{\pi}{4}\right)^{\frac{n}{2}}.$$

For $n \geq 1$ the sequence $(\frac{n^n}{n!})$ is increasing, so

$$\sqrt{|\text{disc}(R)|} \geq \frac{1}{2} \pi^{\frac{n}{2}} > 1,$$

when $n \geq 2$; hence some prime number $p$ divides $|\text{disc}(R)|$. From Theorem 13.14, $p$ is ramified in $R$. \[\square\]

The Minkowski bound (or equivalent bound) is useful in determining the class number. In particular, if $\lambda$ is less than 2, then the class number is 1, because every ideal class contains the unique ideal with norm 1, namely $R$.

For example, consider the quadratic number field $K = \mathbb{Q}(\sqrt{5})$. From Exercise 11.4 we know that $\text{disc}(O_K) = 5$. Also, there are no complex embeddings of $K$ into $\mathbb{C}$. Therefore $\lambda = \frac{2}{\sqrt{5}} \sqrt{5} = \frac{2\sqrt{5}}{2} < 2$ and the class number is 1.

As a second example, we take the quadratic number field $L = \mathbb{Q}(\sqrt{-2})$. From the example before Exercise 11.4, we know that $\text{disc}(O_L) = -8$. As there are two complex embeddings of $L$ into $\mathbb{C}$, we have $\lambda = \frac{4}{\sqrt{8}} \sqrt{-2} = \frac{2}{2} \sqrt{-2} < 2$, so, as in the first example, the class number is 1.

### 14.4 Dirichlet’s unit theorem

Let $K$ be a number field of degree $n$ over $\mathbb{Q}$. We recall that, if $\alpha \in O_K$ is a unit, then $N_{K/\mathbb{Q}}(\alpha) = \pm 1$ (Proposition 11.3).

We define the monomorphism $\phi$ as in Section 14.1 and let $U_K$ be the set of units in $O_K$.

As in Section 14.1, we let $r$ be the number of real and $2s$ the number of complex embeddings of $K$ into $\mathbb{C}$ ($n = r + 2s$). The complex embeddings arise in pairs, namely $\tau_i$ and $\bar{\tau}_i$, for $i = 1, \ldots, s$.

For $I = 1, \ldots, s$, let us set $\sigma_I = \tau_i$. We define a new mapping $\lambda : O_K^* \rightarrow \mathbb{R}^{r+s}$, which we will refer to as the logarithmic mapping, by

$$\lambda(\alpha) = (\ln |\sigma_1(\alpha)|, \ldots, \ln |\sigma_r(\alpha)|, 2\ln |\sigma_{r+1}(\alpha)|, \ldots, 2\ln |\sigma_{r+s}(\alpha)|).$$

**Proposition 14.3** Let $Y$ be a bounded subset of $\mathbb{R}^{r+s}$ and $X = \{\alpha \in O_K^* : \lambda(\alpha) \in Y\}$. Then $X$ is a finite set.

**Proof** As $Y$ is bounded, all the coordinates of $\lambda(\alpha)$ are bounded and it follows that the elements $|\sigma_i(\alpha)|$ belong to a bounded interval. Hence the absolute values of the elementary symmetric...
functions of the $\sigma_i(\alpha)$ lie in some bounded interval. However, the elementary symmetric functions of the $\sigma_i(\alpha)$ are the coefficients of the characteristic polynomial of $\alpha$ (Proposition 10.2), which is a power of the minimal polynomial $m(\alpha, Q)$ (Proposition 10.1). As this polynomial has integer coefficients, there is a real bounded interval containing the coefficients of the characteristic polynomial of $\alpha$ and these are all integers. Therefore there can only be a finite number of characteristic polynomials of elements $\alpha$ belonging to $X$. Since $\alpha$ is a root of its characteristic polynomial, $X$ is a finite set.

**Corollary 14.2** The kernel $G$ of $\lambda$ is a finite group.

**Proof** To see that $G$ is finite, it is sufficient to take $Y = \{0\}$ in Proposition 14.3. We also need to show that $G$ is a group. If $\alpha \in G$, then $|\sigma_i(\alpha)| = 1$, for all $i$, From Proposition 10.2,

$$|N_{K/Q}(\alpha)| = \prod_{i=1}^{n} |\sigma_i(\alpha)| = 1,$$

so $\alpha$ is a unit. Therefore $G$ is the kernel of $\lambda$ restricted to $U_K$, which is a homomorphism. Hence $G$ is a group. □

We now examine $G$ in more detail.

**Proposition 14.4** The kernel $G$ of $\lambda$ consists of all the roots of unity of $K$ and is cyclic.

**Proof** As $G$ is a finite subgroup of $K^*$, by Theorem 3.3, $G$ is cyclic. If $n$ is the order of $G$ and $\alpha \in G$, then $\alpha^n = 1$, hence all elements of $G$ are roots of unity.

Suppose that $\alpha \in K$ and $\alpha^m = 1$, for some $m \in \mathbb{N}$. Then $\alpha \in O_K$ and, for every $i$, with $i = 1, \ldots, r + s$,

$$|\sigma_i(\alpha)|^m = |\sigma_i(\alpha^m)| = |1| = 1.$$

Thus, for all $i$, $|\sigma_i(\alpha)| = 1$, so $\ln |\sigma_i(\alpha)| = 0$, which implies that $\alpha \in G$. □

We now turn to the analysis of the group of units $U_K$. We recall that a subgroup $H$ of a topological group $G$ is discrete if the topology induced on $H$ is discrete. For example, $(\mathbb{Z}^n, +)$ is a discrete subgroup of $(\mathbb{R}^n, +)$ with the usual metric topology.

**Proposition 14.5** If $K$ is a number field, then its group of units $U_K$ is finitely generated and there exists $t \leq r + s$ such that $U_K$ is isomorphic to the product $G \times \mathbb{Z}^t$.

**Proof** From Proposition 14.3, every bounded subset of $\mathbb{R}^{r+s}$ contains only a finite number of elements of $\lambda(U_K)$, hence $\lambda(U_K)$ is a discrete subgroup of $\mathbb{R}^{r+s}$. From Theorem G.6, there exists $t \leq r + s$ such that $\lambda(U_K)$ is a lattice in $\mathbb{R}^t$, hence a free abelian group of rank $t$ (Corollary G.1). By the first isomorphism theorem $\lambda(U_K)$ is isomorphic to the quotient group $U_K/G$, hence $U_K/G$ is a free abelian group of rank $t$, which we write multiplicatively. If $\mathcal{B} = \{g_\alpha_1, \ldots, g_\alpha_t\}$ is a basis of $U_K/G$ and $G\alpha$ belongs to $U_K/G$, then $G\alpha$ is a finite product of powers of the $g_\alpha$:

$$G\alpha = G\alpha_1^{k_1} \cdots G\alpha_t^{k_t} = G\alpha_1^{k_1} \cdots \alpha_t^{k_t},$$

where the $k_i$ are unique. Thus there exists $\beta \in G$ such that $\alpha = \beta \alpha_1^{k_1} \cdots \alpha_t^{k_t}$. Clearly, $\beta$ is unique. From Proposition 14.4, $G$ is cyclic, so $U_K$ is finitely generated. We also notice that the mapping

$$g : U_K \rightarrow G \times \mathbb{Z}^t, \alpha \mapsto (\beta, k_1, \ldots, k_t)$$

209
is a group isomorphism.

We will now aim to make precise the value of $t$. If $\alpha \in U_K$ then

$$\pm 1 = N_{K/Q}(\alpha) = \prod_{i=1}^{n} \sigma_i(\alpha) = \prod_{i=1}^{r} \sigma_i(\alpha) \prod_{j=r+1}^{r+s} \sigma_j(\alpha) \sigma_j(\alpha),$$

which implies that

$$0 = \sum_{i=1}^{r} \ln |\sigma_i(\alpha)| + \sum_{j=r+1}^{r+s} 2 \ln |\sigma_j(\alpha)|.$$

Thus $\lambda(\alpha)$ belongs to the hyperplane

$$H = \{ (x_1, \ldots, x_{r+s}) : \sum_{i=1}^{r+s} x_i = 0 \},$$

which has dimension $r + s - 1$. Hence $\lambda(U_K)$ may be considered a discrete subgroup of $\mathbb{R}^{r+s-1}$ and it follows that $\lambda(U_K)$ is a lattice in $\mathbb{R}^t$, where $t \leq r + s - 1$ (Theorem G.6). Therefore $\lambda(U_K)$ is a free abelian group of rank $t \leq r + s - 1$ (Corollary G.1). This improves our estimate of $t$ found in the proof of Proposition 14.5, where we only found that the rank $t$ of $\lambda(U_K)$ was bounded by $r + s$. It follows that $U_K$ is isomorphic to the product $G \times \mathbb{Z}^t$, with $t \leq r + s - 1$.

If $r + s = 1$, then $t = 0$ and $U_K$ is isomorphic to the group $G$. In fact, in all cases we have equality, i.e., $t = r + s - 1$. This is the content of Dirichlet’s unit theorem, which we will now prove. The proof is much longer than those of the results we have encountered up to now in this section.

**Theorem 14.6** The group $U_K$ of the number field $K$ is isomorphic to the product $G \times \mathbb{Z}^t$, where $G$ is the finite cyclic group consisting of all the roots of unity in $K$ and $t = r + s - 1$.

**Proof** We have already covered the case where $r + s = 1$, so we will suppose that $r + s > 1$. Let $W$ be the $\mathbb{R}$-span of $\lambda(U_K)$. Above we defined a certain hyperplane $H$. Since $\lambda(U_K)$ is contained in $H$, $W$ is a subspace of $H$. We aim to show that $W = H$. To do so, it is sufficient to prove that $W^\perp \subset H^\perp$, or equivalently that $x \notin W^\perp \Rightarrow x \notin H^\perp$. We fix $x = (x_1, \ldots, x_{r+s}) \notin H^\perp$ and define a function $f : K^* \rightarrow \mathbb{R}$ by

$$f(\alpha) = x_1 \ln |\sigma_1(\alpha)| + \cdots + x_r \ln |\sigma_r(\alpha)| + x_{r+1} 2 \ln |\sigma_{r+1}(\alpha)| + x_{r+s} 2 \ln |\sigma_{r+s}(\alpha)|.$$

To show that $x \notin W^\perp$ we will find $u \in U_K$ such that $f(u) \neq 0$. We will proceed by steps.

**Step 1:** An application of Minkowski’s theorem

Let

$$A = \sqrt{\text{disc}(O_K)} \left( \frac{2}{\pi} \right)^s \in \mathbb{R}^*_+. $$

and let us choose $c_1, \ldots, c_{r+s} \in \mathbb{R}^*_+$ such that

$$c_1 \cdots c_r \cdot (c_{r+1} \cdots c_{r+s})^2 = A.$$
We define $S$ to be the subset of $\mathbb{R}^n$ composed of elements $(x_1, \ldots, x_n)$ such that, for $i = 1, \ldots, r$, $|x_i| \leq c_i$, and $x_{r+1}^2 + x_{r+2}^2 \leq c_{r+1}^2$, $x_{r+3}^2 + x_{r+4}^2 \leq c_{r+2}^2$, $\ldots$, $x_{2r+1}^2 \leq c_{r+s}^2$. We may view $S$ as a product of $r$ intervals and $s$ discs. We obtain

$$\text{vol}(S) = \prod_{i=1}^{r} (2c_i) \prod_{i=r+1}^{r+s} (\pi c_i^2) = 2^r \pi^s A.$$ 

We may associate a lattice $\Lambda_{O_K} (= \phi(O_K))$ with $O_K$. From Section 14.1 we have

$$\text{det} \Lambda_{O_K} = 2^{-s} \sqrt{|\text{disc}(O_K)|}$$

and so

$$2^r \pi^s A = 2^r \pi^s \sqrt{|\text{disc}(O_K)|} = 2^r \pi^s \text{det} \Lambda_{O_K} = 2^n \text{det} \Lambda_{O_K},$$

i.e.,

$$\text{vol}(S) = 2^n \text{det} \Lambda_{O_K}.$$ 

From Minkowski’s theorem (Theorem G.4), $S$ contains a nonzero lattice point, i.e., the set $S \cap \phi(O_K)$ contains a nonzero element. Therefore there exists $\beta \in O_K$ which is nonzero and such that $|\sigma_i(\beta)| \leq c_i$, for $i = 1, \ldots, r + s$.

**Step 2: Properties of the point $\beta$**

First we consider the norm of $\beta$. To simplify the notation, for $i = 1, \ldots, s$, we set $\sigma_{r+i} = \tau_i$ and $\sigma_{r+s+i} = \tau_i$. Then

$$|N_{K/Q}(\beta)| = \prod_{i=1}^{r} |\sigma_i(\beta)| \prod_{i=r+1}^{r+s} |\sigma_i(\beta)|^2 \leq c_1 \cdots c_r \cdot (c_{r+1} \cdots c_{r+s})^2 = A.$$

As $\beta$ is nonzero we also have $|N_{K/Q}(\beta)| \geq 1$, because the norm of an algebraic integer is an integer. Thus we have $1 \leq |N_{K/Q}(\beta)| \leq A$.

We now use the norm to estimate the values of the elements $|\sigma_i(\beta)|$. Suppose that for some $i \leq r$ we have $|\sigma_i(\beta)| < \frac{A}{4}$. Then

$$1 \leq |N_{K/Q}(\beta)| < c_1 \cdots \frac{c_i}{A} \cdots c_r \cdot (c_{r+1} \cdots c_{r+s})^2 = \frac{A}{A} = 1,$$

a contradiction, so $|\sigma_i(\beta)| \geq \frac{A}{4}$, for $i = 1, \ldots, r$. In the same way, $|\sigma_i(\beta)|^2 \geq \frac{c_i^2}{A}$, for $i = r + 1, \ldots, r + s$. Thus we have

211
\[ \frac{c_i}{|\sigma_i(\beta)|} \leq A, \quad i = 1, \ldots, r \quad \text{and} \quad \left( \frac{c_i}{|\sigma_i(\beta)|} \right)^2 \leq A, \quad i = r + 1, \ldots, r + s. \quad (14.3) \]

From Theorem 13.5, there is only a finite number of ideals in \( O_K \) of a given norm, therefore there exists a finite number of nonzero principal ideals \((\gamma_1), \ldots, (\gamma_m)\) of norm at most \( A \). Since \( \|((\beta)) = |N_{K/Q}(\beta)| \leq A \), we must have \( (\beta) = (\gamma_k) \), for some \( k \), so there exists a unit \( u \in O_K \) such that \( \beta = u\gamma_k \).

Step 3: Showing that \( f(u) \neq 0 \)

For the point \( x \notin H^\perp \) we define
\[
\alpha = a(c_1, \ldots, c_{r+s}) = x_1 \ln c_1 + \cdots + x_{r+1} \ln c_{r+1} + \cdots.
\]

We recall the definition of the function \( f : K^* \to \mathbb{R} \):
\[
f(\alpha) = x_1 \ln |\sigma_1(\alpha)| + \cdots + x_{r+1} \ln |\sigma_{r+1}(\alpha)| + \cdots.
\]

Then
\[
|f(u) - a| = |f(\beta) - f(\gamma_k) - a| \\
\leq |f(\gamma_k)| + |a - f(\beta)| \\
= |f(\gamma_k)| + |x_1 (\ln c_1 - \ln |\sigma_1(\beta)|) + \cdots + 2x_{r+1} (\ln c_{r+1} - \ln |\sigma_{r+1}(\beta)|) + \cdots| \\
= |f(\gamma_k)| + |x_1 \ln \left( \frac{c_1}{|\sigma_1(\beta)|} \right) + \cdots + x_{r+1} \ln \left( \frac{c_{r+1}}{|\sigma_{r+1}(\beta)|} \right)^2 + \cdots| \\
\leq |f(\gamma_k)| + \ln A \sum_{i=1}^{r+s} |x_i| \\
\leq \max f(\gamma_k)| + \ln A \sum_{i=1}^{r+s} |x_i| = B.
\]

where we have used the equations (14.3). If we can find \( a \), which depends on the \( c_i \), such that \( |a| > B \), then \( |f(u) - a| \leq B \) would imply that \( |f(u)| > 0 \). We will now show that it is possible to find such an element \( a \).

We recall the definition of the hyperplane \( H \):
\[
H = \{z = (z_1, \ldots, z_{r+s}) \in \mathbb{R}^{r+s} : \sum_{i=1}^{r+s} z_i = 0\}.
\]

Since \( H^\perp \) is the vector subspace generated by the vector
\[
v = (1, \ldots, 1) \in \mathbb{R}^{r+s},
\]

\( x \notin H^\perp \) implies that we cannot have \( x_1 = \cdots = x_{r+s} \). To simplify the notation, we set \( d_i = c_i \), for \( i = 1, \ldots, r \) and \( d_i = c_i^2 \), for \( i = r + 1, \ldots, r + s \). Then
\[
a = x_1 \ln d_1 + \cdots + x_{r+s} \ln d_{r+s}
\]

212
and \( \prod_{i=1}^{r+s} d_i = A \). As already stated there exist \( x_i \neq x_j \). Without loss of generality, let us suppose that \( i = 1 \) and \( j = 2 \). If we set \( d_3 = \cdots = d_{r+s} = 1 \), then \( d_1 d_2 = A \) and

\[
|a| = | \sum_{i=1}^{r+s} x_i \ln d_i | = | x_1 \ln d_1 + x_2 \ln d_2 |
\]

\[
= | x_1 \ln d_1 + x_2 \ln \frac{A}{d_1} |
\]

\[
= | (x_1 - x_2) \ln d_1 + x_2 \ln A | \rightarrow \infty,
\]

when \( d_1 \rightarrow \infty \). Hence we can find an element \( a \) such that \( |a| > B \) and so \( W = H \).

In Proposition 14.5 we saw that there are elements \( \alpha_1, \ldots, \alpha_t \in U_K \) such that for any element \( \alpha \in U_K \) we have \( \alpha = \beta \alpha_1^{k_1} \cdots \alpha_t^{k_t} \), where \( \beta \) is a root of unity. Then

\[
\lambda(\alpha) = \lambda(\beta \alpha_1^{k_1} \cdots \alpha_t^{k_t}) = k_1 \lambda(\alpha_1) + \cdots + k_t \lambda(\alpha_t).
\]

It follows that the set \( B = \{ \lambda(\alpha_1), \ldots, \lambda(\alpha_t) \} \) is a generating set of \( W \) and hence of \( H \). Given that the dimension of \( H \) is \( r + s - 1 \), we have \( t \geq r + s - 1 \). However, we know that \( t \leq r + s - 1 \), so we have \( t = r + s - 1 \). We deduce that \( B \) is a basis of the vector space \( H \). Also, \( \lambda(U_K) \) is a free abelian group of rank \( t \) and the elements of \( B \) form an independent generating set, so \( B \) is also a basis of the free abelian group \( \lambda(U_K) \).

Dirichlet’s unit theorem implies that there are \( t = r + s - 1 \) particular units in \( O_K \) such that any unit \( \alpha \in O_K \) can be expressed uniquely in the form

\[
\alpha = \beta \alpha_1^{k_1} \cdots \alpha_t^{k_t},
\]

with \( \beta \) a root of unity and the \( k_i \) in \( \mathbb{Z} \). The set \( \{ \alpha_1, \ldots, \alpha_t \} \), which is not unique, is called a fundamental system of units.

As an example, let us consider the cyclotomic field \( K = \mathbb{Q}(\zeta) \), where \( \zeta = e^{2\pi i/p} \), with \( p \) an odd prime number. The degree of the extension \( K \) over \( \mathbb{Q} \) is \( p - 1 \) and so there are \( p - 1 \) embeddings in \( \mathbb{C} \). As the applications \( \sigma_j \), with \( \sigma_j(\zeta) = \zeta^j \), for \( j = 1, \ldots, p - 1 \), are distinct embeddings, all the embeddings are complex, i.e., \( r = 0, 2s = p - 1 \), which implies that \( t = 0 + \frac{p - 1}{2} = \frac{p - 3}{2} \). If \( p = 3 \), then the only units are the roots of unity. If \( p \geq 5 \), then there is an infinite number of units.

If \( K = \mathbb{Q}(\sqrt{m}) \) is an imaginary quadratic field, then there are no real embeddings and so \( 2s = n = 2 \implies s = 1 \implies t = 0 \), so again the only units are the roots of unity.

Now we consider real quadratic fields, which are more interesting. If \( K = \mathbb{Q}(\sqrt{m}) \) is a real quadratic field, then there are no imaginary embeddings in \( \mathbb{C} \), so \( s = 0 \) and \( r = 2 \). Thus \( t = 1 \) and there is an infinite number of units. There are only two roots of unity, namely \( \pm 1 \), hence there exists an element \( x \in U_K \) such that the elements \( u \in U_K \) can be written \( u = \pm x^n \), with \( n \in \mathbb{Z} \). If \( u \) is a unit, then so are \( -u, \frac{1}{u} \) and \( -\frac{1}{u} \). This implies that there are units \( u \) with \( u > 1 \).

Let us set \( U_K^+ \) for the set of such units. The elements of \( U_K \) can be determined from those of \( U_K^+ \): for any unit \( u \in U_K \) if and only if there exists \( v \in U_K^+ \) such that \( u = \pm v \) or \( u = \pm \frac{1}{v} \).

Let us look more closely at the set \( U_K^+ \). If \( v \in U_K^+ \), then \( v = \pm x^n \), which implies that \( v = |x|^n \). Clearly \( |x| \in U_K \). If \( |x| < 1 \), then we may replace \( x \) by \( \frac{1}{x} \), which ensures that \( v = |x|^n \), with \( n \in \mathbb{N}^* \). It is clear that \( |x| \) is the minimum of \( U_K^+ \) and that the elements of \( U_K^+ \) are the positive
The algebraic integers are of the form $a + b\sqrt{m}$, with $a, b \in \mathbb{Z}$ (see the proof of Theorem 11.6). The units are those whose norm is $\pm 1$, i.e., $a^2 - b^2m = \pm 1$. We seek the smallest such element whose value is greater than 1. Here is a simple method to find it: Compute $mb^2$ for $b = 1, 2, 3 \ldots$ until either $mb^2 + 1$ or $mb^2 - 1$ is a square $a^2$, where $a > 0$. Then set $u = a + b\sqrt{m}$. $u$ is the fundamental unit.

**Remark** We have seen here that all the embeddings of the number field $K$ into $\mathbb{C}$ may be real. In this case we say that $K$ is totally real. Then the units in $O_K$ are the roots of unity and so $U_K$ is finite. On the other hand, it may be so that no embedding is real. In this case we say that $K$ is totally imaginary.

**Exercise 14.3** Show that a number field $K$ which is a normal extension of $\mathbb{Q}$ is either real or imaginary.

### 14.5 Hermite’s theorem

In this section we will see another application of Minkowski’s theorem (Theorem G.4). We will show that for any given positive integer there is only a finite number of number fields whose ring of integers has a discriminant equal to the positive integer in question. We will begin with a preliminary result.

**Proposition 14.6** Let $K$ be a number field of degree $n$ and $r$ (resp. $2s$) the number of real (resp. complex) embeddings of $K$ into $\mathbb{C}$. If $I$ is a nonzero ideal in $O_K$ and $c_1, \ldots, c_{r+s}$ positive constants such that

$$\prod_{i=1}^{r+s} c_i > \left(\frac{2}{\pi}\right)^s |\text{disc}(O_K)|^{\frac{n}{2}} |I|,$$

then...
then there exists a nonzero in \( I \), with \( |\sigma_i(\alpha)| < c_i \) for \( 1 \leq i \leq r \), and \( |\sigma_{r+j}(\alpha)|^2 < c_{r+j} \), for \( 1 \leq j \leq s \).

**Proof** Consider the region
\[
X(c) = \{ x = (y, z) \in \mathbb{R}^n \cong \mathbb{R}^r \times \mathbb{C}^s : |y_i| < c_i, 1 \leq i \leq r; |z_j|^2 < c_{r+j}, 1 \leq j \leq s \}.
\]
It is clear that \( X(c) \) is convex and centrally symmetric. Also
\[
\mu(X(c)) = 2^r \pi^r \prod_{i=1}^{r+s} c_i > 2^r \pi^r \left( \frac{2}{\pi} \right)^s |\text{disc}(O_K)|^{\frac{1}{2}} \| I \|
\]

where \( \mu \) denotes Lebesgue measure on \( \mathbb{R}^n \). In Section 14.1 we saw that
\[
\det \Lambda_I = 2^{-s} |\text{disc}(O_K)|^{\frac{1}{2}} \| I \| \implies \mu(X(c)) > 2^n \det \Lambda_I.
\]

From Minkowski’s theorem there exists an \( \alpha \in I \) such that \( \phi(\alpha) \neq 0 \) and \( \phi(\alpha) \in \Lambda_I \cap X(c) \). Thus we have \( \alpha \neq 0 \) and \( |\sigma_i(\alpha)| < c_i \) for \( 1 \leq i \leq r \), and \( |\sigma_{r+j}(\alpha)|^2 < c_{r+j} \), for \( 1 \leq j \leq s \), as required. \( \square \)

We are now in a position to establish Hermite’s theorem.

**Theorem 14.7** For a fixed positive integer \( d \) there exist only finitely many number rings \( O_K \) such that \( \text{disc}(O_K) = d \).

**Proof** If \( K \) is a number field and \( [K : \mathbb{Q}] = n \), then there is an ideal \( I \) in \( O_K \) such that
\[
\| I \| \leq \frac{n!}{n^n} \left( \frac{4}{\pi} \right)^s |\text{disc}(O_K)|^{\frac{1}{2}} \implies \frac{n^n}{n!} \left( \frac{\pi}{4} \right)^s \leq |\text{disc}(O_K)|^{\frac{1}{2}};
\]
because \( \| I \| \geq 1 \). Hence the degree of the extension is bounded and so it is sufficient to prove that there is only a finite number of number rings with a given discriminant when the degree of the corresponding number field has a certain value. We consider two cases: (1) \( K \) has a real embedding in \( \mathbb{C} \), (2) all embeddings of \( K \) in \( \mathbb{C} \) are complex.

**Case 1** In this case \( r > 0 \). We choose real numbers \( c_i \), for \( 1 \leq i \leq r + s \), such that \( c_1 > 1, c_i < 1 \) for \( i > 1 \) and
\[
\prod_{i=1}^{r+s} c_i > \left( \frac{2}{\pi} \right)^s |\text{disc}(O_K)|^{\frac{1}{2}}.
\]
From Proposition 14.6 there exists a nonzero \( \alpha \in O_K \) such that \( |\sigma_i(\alpha)| < c_i \), for \( 1 \leq i \leq r \), and \( |\sigma_{r+j}(\alpha)|^2 < c_{r+j} \), for \( 1 \leq j \leq s \). Since
\[
1 \leq |N_{K/\mathbb{Q}}(\alpha)| = |\sigma_1(\alpha)| \prod_{i=2}^{r} |\sigma_i(\alpha)| \prod_{j=1}^{s} |\sigma_{r+j}(\alpha)|^2,
\]
we have \( |\sigma_1(\alpha)| > 1 \) and \( |\sigma_i(\alpha)| < 1 \), for \( \sigma_i \neq \sigma_1 \). Hence \( \sigma_1(\alpha) \neq \sigma_i(\alpha) \), if \( i \neq 1 \).

**Case 2** We define a centrally symmetric convex region \( X \) of \( \mathbb{C}^s \) as follows:
\[
X = \{ z \in \mathbb{C}^s : |\Re(z_1)| < \frac{1}{2}, |\Im(z_1)| < c_1, |z_j|^2 < c_j = \frac{1}{2}, 2 \leq j \leq s \},
\]

\[
215
\]
where \( c_1 \) is some constant such that \( \mu(X) > 2^n 2^{-s} \text{disc}(O_K)^{1/2} = 2^n \det \Lambda \). From Minkowski’s theorem there exists a nonzero \( \alpha \in O_K \) such that \( \phi(\alpha) \in X \cap \Lambda \), where \( \phi \) is the usual monomorphism of \( K \) into \( \mathbb{C} \). Therefore we have \( |\Re(\sigma_1(\alpha))| < \frac{1}{2}, |\Im(\sigma_1(\alpha))| < c_1 \) and \( |\sigma_j(\alpha)|^2 < \frac{1}{2}, \) for \( 2 \leq j \leq s \). Now

\[
1 \leq |N_{K/\mathbb{Q}}(\alpha)| = |\sigma_1(\alpha)|^2 \prod_{j=2}^{s} |\sigma_j(\alpha)|^2 \implies |\sigma_1(\alpha)|^2 > 1.
\]

Therefore, if \( 2 \leq j \leq s \), we have \( \sigma_j(\alpha) \neq \sigma_1(\alpha) \). (As \( |\sigma_1(\alpha)| > 1 \) and \( |\Re(\sigma_1(\alpha))| < \frac{1}{2} \), we must have \( |\Im(\sigma_1(\alpha))| > \frac{\sqrt{3}}{2} \).

In both cases we have \( n = [\mathbb{Q}(\alpha) : \mathbb{Q}] \). If this is not the case, then \([K : \mathbb{Q}(\alpha)] = m \geq 2\) and \( \sigma_1 \) restricted to \( \mathbb{Q}(\alpha) \) may be extended to \( K \) in \( m \) distinct ways (Theorem 3.2), which implies that there exists \( \sigma_i \neq \sigma_1 \) such that \( \sigma_i(\alpha) = \sigma_1(\alpha) \), a contradiction. It follows that \([K : \mathbb{Q}(\alpha)] = 1\), i.e., \( K = \mathbb{Q}(\alpha) \). If \( f = m(\alpha, \mathbb{Q}) \), then \( \deg f = n \) and \( f \in \mathbb{Z}[X] \).

From Proposition 10.2 we have

\[
\text{char}_{K/\mathbb{Q}}(\alpha) = \prod_{i=1}^{n} (-\sigma_i(\alpha) + X) \in \mathbb{Z}[X],
\]

because \( \text{char}_{K/\mathbb{Q}}(\alpha) \) is a power of \( f \), by Corollary 10.1. Also, as the \( c_i \) are bounded, so are the coefficients of \( \text{char}_{K/\mathbb{Q}}(\alpha) \) and it results that the coefficients of \( f \) are all bounded. We now observe that there can only be a finite number of polynomials in \( \mathbb{Z}[X] \) with all the coefficients bounded. Let us write \( \mathcal{P}(c) \) for the set of such polynomials obtained here. If \( K \) is a number field whose ring of integers \( O_K \) has discriminant \( d \) and \([K : \mathbb{Q}] = n\), then, from what we have seen, there exists \( \alpha \) with minimal polynomial \( f \) in \( \mathcal{P}(c) \) such that \( K = \mathbb{Q}(<\alpha>) \). As a polynomial has a finite number of roots, there can only be a finite number of number fields with \( K = \mathbb{Q}(\alpha) \) and \( \alpha \) a root of a polynomial in \( \mathcal{P}(c) \). This finishes the proof. \( \square \)
Chapter 15

Differents

In this chapter we introduce the different, which, as the norm, trace and discriminant, plays an important role in algebraic number theory. We will define the different and then consider its properties. As the definition requires quite a lot of preliminary work, we will consecrate a section to it.

15.1 Definition of the different

Let $C$ be a Dedekind domain and $K$ its field of fractions. Suppose that $L$ is an $n$-dimensional separable extension of $K$ and $D$ the integral closure of $C$ in $L$. From Theorem 12.15, $D$ is also a Dedekind domain and, from Proposition 11.2, $L$ is the field of fractions of $D$. We consider the bilinear form $B$ defined on $L \times L$ by $(x,y) \mapsto T_{L/K}(xy)$. This is nondegenerate, because $L$ is a separable extension of $K$ (see Corollary 10.4). From Lemma 12.8, we know that if $B = \{x_1, \ldots, x_n\}$ is a basis of $L$ over $K$, then $B$ has a dual basis $B^* = \{x_1^*, \ldots, x_n^*\}$, i.e., $B(x_i, x_j^*) = \delta_{ij}$, where $\delta_{ij}$ is the Kronecker symbol.

**Proposition 15.1** Let $L$ be a separable $n$-dimensional extension of $K$ and $B$ the nondegenerate bilinear form on $L \times L$ defined above. We suppose that $\{x_1, \ldots, x_n\}$ is a basis of $L$ over $K$ and $\{x_1^*, \ldots, x_n^*\}$ its dual basis. Then

$$\text{disc}_{L/K}(x_1, \ldots, x_n) \cdot \text{disc}_{L/K}(x_1^*, \ldots, x_n^*) = 1.$$ 

**Proof** Let $\sigma_1, \ldots, \sigma_n$ be the $K$-monomorphisms of $L$ into an algebraic closure $C$ of $K$. We set $X = (\sigma_i(x_j))$ and $X^* = (\sigma_i(x_j^*))$. Then

$$X^*x = (T_{L/K}(x_i^*x_j)),$$

therefore

$$\det X^* \det X = \det I_n = 1.$$ 

However,

$$\text{disc}_{L/K}(x_1, \ldots, x_n) = (\det X)^2 \quad \text{and} \quad \text{disc}_{L/K}(x_1^*, \ldots, x_n^*) = (\det X^*)^2,$$

therefore

$$\text{disc}_{L/K}(x_1, \ldots, x_n) \cdot \text{disc}_{L/K}(x_1^*, \ldots, x_n^*) = 1.$$
as required.

For a subset $M$ of $L$, we define

$$M^* = \{ x \in L : T_{L/K}(xy) \in C, \forall y \in M \}.$$ 

$M^*$ is called the complementary subset of $M$. In the next proposition we consider some elementary properties of complementary subsets.

**Proposition 15.2** We have

- **a.** $M^*$ is a $C$-module. If $DM \subset M$, then $M^*$ is a $D$-module.
- **b.** $M_1 \subset M_2 \implies M_2^* \subset M_1^*$.
- **c.** $D \subset D^*$ and $T_{L/K}(D^*) \subset C$.
- **d.** If $M$ is a free $C$-module with basis $B = \{ x_1, \ldots, x_n \}$, then $M^*$ is a free $C$-module with basis $\{ x_1^*, \ldots, x_n^* \}$ and $M^{**} = M$.

(The basis $B$ is also a basis of the vector space $L$ over $K$, so has a dual basis $B^* = \{ x_1^*, \ldots, x_n^* \}$ in $L$.)

**Proof.**

**a.** Let $x_1, x_2 \in M^*$ and $y \in M$. Then

$$T_{L/K}(x_1 + x_2)y = T_{L/K}(x_1y) + T_{L/K}(x_2y) \in C,$$

so $x_1 + x_2 \in M^*$. If $a \in C$, $x \in M^*$ and $y \in M$, then

$$T_{L/K}((ax)y) = aT_{L/K}(xy) \in C,$$

so $ax \in M^*$. We have shown that $M^*$ is $C$-module.

Suppose now that $DM \subset M$. If $b \in D$, $x \in M^*$ and $y \in M$, then

$$T_{L/K}((bx)y) = T_{L/K}(x(by)) \in C,$$

because $by \in M$. Hence $bx \in M^*$ and it follows that $M^*$ is a $D$-module.

**b.** The proof of this part is elementary.

**c.** Let $x \in D$. As $x$ is integral over the integrally closed domain $C$, from Proposition 11.1 the minimal polynomial $m(x, K)$ has coefficients in $C$. However, the characteristic polynomial $\text{char}_{L/K}(x)$ is a positive power of $m(x, K)$ (Proposition 10.1), therefore the coefficients of $\text{char}_{L/K}(x)$ belong to $C$, in particular $T_{L/K}(x) \in C$. Thus $T_{L/K}(D) \subset C$. If $x, y \in D$, then $xy \in D$ and so $T_{L/K}(xy) \in C$, which implies that $x \in D^*$ and it follows that $D \subset D^*$.

By definition, if $x \in D^*$, then $T_{L/K}(xy) \in C$, for all $y \in D$. As $1 \in D$, $T_{L/K}(x) \in C$ and so $T_{L/K}(D^*) \subset C$.

**d.** We know that $B^*$ is a basis of $L$ over $K$. To show that $B^*$ is a basis of $M^*$, we first need to establish the inclusion of $B^*$ in $M^*$. If $x_i^* \in B^*$, then, for $x_j \in B$, we have

$$T_{L/K}(x_i^*x_j) = \delta_{ij} \in C \implies T_{L/K}(x_i^*y) \in C, \forall y \in M,$$

because $\{x_1, \ldots, x_n\}$ is a $C$-basis of $M$. Thus $x_i^* \in M^*$, for all $i$. 218
As \( B^* \) is independent over \( K \), this is also the case over \( C \), which is a subset of \( K \). To show that \( B^* \) is a basis of \( M^* \), we need to show that it is a generating set. As \( B^* \) is a basis of \( L \) over \( K \), for \( x \in M^* \), we have \( x = \sum_{i=1}^{n} a_i x_i^* \), with \( a_i \in K \). It is sufficient to show that the \( a_i \in C \). We have
\[
a_j = T_{L/K} \left( \sum_{i=1}^{n} a_i x_i^* \right) \in C \quad \forall j \implies a_j \in C,
\]
Thus \( B^* \) is a generating set of \( M^* \).

We now turn to the second part of \( d \). \( M^* \) is composed of those elements \( x \in L \) which can be written in the form \( x = \sum_{i=1}^{n} a_i x_i^* \), with \( a_i \in C \), for all \( i \). Replacing \( M \) by \( M^* \), we see that \( M^{**} \) is composed of those elements \( x \in L \) which can be written in the form \( x = \sum_{i=1}^{n} a_i x_i^{**} \), with \( a_i \in C \), for all \( i \). As \( x_i^{**} = x_i \), for all \( i \), we have
\[
M^{**} = M,
\]
as claimed. \( \square \)

We now concentrate our attention on \( D^* \). For the next proposition we will need two standard results on Noetherian rings. Proofs may be found, for example, in [1].

**Lemma 15.1**  
\( \bullet \) **a.** If \( M \) is a finitely generated module over a Noetherian ring \( R \), then \( M \) is noetherian.

\[ \bullet \] **b.** A submodule of a noetherian module is finitely generated.

**Proposition 15.3** \( D^* \) is a fractional ideal of \( D \).

**Proof** As \( DD \subset D \), from Proposition 15.2 **a.**, \( D^* \) is a \( D \)-module (contained in the field of fractions of \( D \)). It is sufficient to show that \( D^* \) is a finitely generated \( D \)-module. (If this is the case, then the product of the denominators of the elements of a generating set provides a denominator of \( D^* \).)

Since the extension \( L/K \) is finite and separable, from the primitive element theorem there exists \( \alpha \in L \) such that \( L = K(\alpha) \). As \( \alpha \) is algebraic over \( K \), the fraction field of \( C \), there exists \( c \in C \setminus \{0\} \) such that \( d = cc \) is is integral over \( C \); then \( d \) belongs to \( D \), the integral closure of \( C \) in \( L \). Moreover, the set \( D = \{1, d, \ldots, d^{n-1}\} \) is a basis of \( L \) over \( K \), since \( [L : K] = n \) and \( L = K(d) \) ensures that the degree of the minimal polynomial \( m(d, K) = n \). The free module \( C \)-module generated by \( D \) is the module \( C[d] \).

As \( C[d] \subset D \), we have \( D^* \subset C[d]^* \), using Proposition 15.2 **b.** Also, \( C \) is a Dedekind domain, hence a noetherian domain, and \( C[d]^* \) is finitely generated over \( C \), so \( C[d]^* \) is a noetherian \( C \)-module (Lemma 15.1 **a.**). Since \( D^* \) is a submodule of the \( C \)-module \( C[d]^* \), \( D^* \) is finitely generated over \( C \) (Lemma 15.1 **b.**). Given that \( C \subset D \), this is also the case over \( D \). \( \square \)

We are now in a position to define the different. We notice that \( D^* \) is nonzero, because \( D \subset D^* \), so it has an inverse in the set of fractional ideals of \( D \). The fractional ideal \( (D^*)^{-1} \) is called the different of \( D \) over \( C \) and is denoted \( \Delta(D/C) \). In the next section, we will see that the different is in fact an integral ideal of \( D \).

**Remark** Suppose that \( K \) and \( L \) are number fields, where \( L \) is a finite extension of \( K \). If we set \( C = \mathbb{O}_K \) and \( D = \mathbb{O}_L \), then \( C \) and \( D \) are Dedekind domains and \( D \) is the integral closure of \( C \) in \( L \). In this case we often write \( \Delta_{L/K} \) for \( \Delta(D/C) \). If \( K = \mathbb{Q} \), then, instead of writing \( \Delta_{L/\mathbb{Q}} \), we often use the shorter form \( \Delta_L \). \( \Delta_L \) is called the absolute different of \( L \).
15.2 Basic properties of the different

As we said at the end of the preceding section, the different is an integral ideal of $D$. We will now prove this.

**Proposition 15.4** The different of $D$ over $C$ is an integral ideal of $D$.

**Proof** As $D \subset D^*$, we have $(D^*)^{-1} \subset D^{-1} = D$, so $(D^*)^{-1}$ is an integral ideal of $D$. \hfill \Box

We may generalize the product of two ideals in the following way. If $R \subset S$ are commutative rings and $I$ (resp. $J$) is an ideal in $R$ (resp. $S$), then we may define the product $JI$ to be the collection of all sums of the form $\sum_{i=1}^{n} x_i y_i$, where $x_i \in I$ and $y_i \in J$. Then clearly $JI$ is an ideal in $S$. In the case where $R$ and $S$ are integral domains, we may generalize the product of fractional ideals in a similar manner.

We recall that $C$ is a Dedekind domain with field of fractions $K$, $L$ a finite separable extension of $K$ and $D$ the integral closure of $C$ in $L$. In addition, let $M$ be finite separable extension of $L$ and $E$ the integral closure of $D$ in $M$. Then $M$ is also a finite separable extension of $K$ and $E$ the integral closure of $C$ in $M$. The different of $D(C)$, $\Delta(E|C)$ and $\Delta(E|D)$ are all defined and related in the following way:

$$\Delta(E|C) = \Delta(E|D)\Delta(D|C).$$

We say that the different is transitive. To prove this result we need a lemma.

**Lemma 15.2** Let $C$ be a Dedekind domain, with field of fractions $K$, $L$ a finite separable extension of $K$ and $D$ the integral closure of $C$ in $L$. Assume that $J$ is a fractional ideal of $D$. Then $T_{L/K}(J) \subset C$ if and only if $J \subset D^*$.

**Proof** Suppose that $T_{L/K}(J) \subset C$. As $J$ is a $D$-module, we have $J = DJ$. If $x \in J$ and $d \in D$, then $T_{L/K}(xd) = T_{L/K}(y)$, with $y \in J$. Thus $T_{L/K}(xd) \in C$ and it follows that $J \subset D^*$.

We now consider the converse. Suppose that $J \subset D^*$. If $x \in J$ and $d \in D$, then $T_{L/K}(xd) \in C$. Setting $d = 1$, we obtain $T_{L/K}(x) \in C$ and it follows that $T_{L/K}(J) \subset C$. \hfill \Box

We may now establish the transitivity of the different referred to above.

**Theorem 15.1** We have

$$\Delta(E|C) = \Delta(E|D)\Delta(D|C).$$

**Proof** To simplify matters, we will proceed in steps. However, first of all we recall that

$$\Delta(E|D)^{-1} = \{ x \in M : T_{M/L}(xy) \in D, \forall y \in E \}$$

and

$$\Delta(E|C)^{-1} = \{ x \in M : T_{M/K}(xy) \in C, \forall y \in E \}.$$  

Also, we will write $D^*$ for $\Delta(D|C)^{-1}$.

**Step 1** If $J_E$ is a fractional ideal of $E$ contained in $\Delta(E|D)^{-1}$, then

$$T_{M/K}(J_{ED^*}) \subset T_{L/K}(D^*).$$

Indeed, if $d \in D$, $d^* \in D^*$ and $j_E \in J_E$, then

$$T_{L/K}(T_{M/L}(j_E d^*) d) = T_{L/K}(dd^*(T_{M/L}(j_E))).$$
because $d^* \in L$. Moreover, $j_E \in \Delta(E|D)^{-1}$ implies that $T_{M/L}(j_E) \in D$. Consequently, $T_{L/K}(T_{M/L}(j_E d^*))d \subset C$, since $d^* \in D^*$. This means that
\[ T_{M/L}(j_E D^*) \subset D^* \implies T_{L/K} \circ T_{M/L}(j_E D^*) \subset T_{L/K}(D^*) \]
and transitivity of the trace ensures that the statement of **Step 1** holds.

**Step 2** $J_E \subset \Delta(E|C)^{-1}D^*$.

From Proposition 15.2 c. and the first step, we have
\[ C \supset T_{L/K}(D^*) \supset T_{M/K}(J_E D^*). \]
Now, using Lemma 15.2, with $L = M$, $D = E$ and $J = J_E D^*$, we obtain
\[ J_E D^* \subset \Delta(E|C)^{-1} \implies J_E \subset \Delta(E|C)^{-1}\Delta(D|C), \]
because $D^* = \Delta(D/C)^{-1}$.

**Step 3** $\Delta(E|C) = \Delta(E|D)\Delta(D|C)$.

Setting $J_E = \Delta(E|D)^{-1}$, we obtain
\[ \Delta(E|D)^{-1} \subset \Delta(E|C)^{-1}\Delta(D|C). \]
Since $C \subset D$, we have $\Delta(E|C)^{-1} \subset \Delta(E|D)^{-1}$ and so
\[ \Delta(E|D)^{-1} \subset \Delta(E|C)^{-1}\Delta(D|C) \subset \Delta(E|D)^{-1}\Delta(D|C) \subset \Delta(E|D)^{-1}, \]
because $\Delta(E|D)^{-1}$ is an $E$-module and $\Delta(D|C) \subset D$. Therefore
\[ \Delta(E|D)^{-1} = \Delta(E|C)^{-1}\Delta(D|C) \implies \Delta(E|C) = \Delta(E|D)\Delta(D|C). \]
This ends the proof.

If we multiply $\Delta(D|C)$ on the left by $E$, we obtain an ideal of $E$ and an analogous expression to that of Theorem 15.1, but involving a multiplication of ideals in $E$.

**Corollary 15.1** We have
\[ \Delta(E|C) = \Delta(E|D)(E\Delta(D|C)). \]

**Proof** It is sufficient to show that
\[ \Delta(E|D)(E\Delta(D|C)) = \Delta(E|D)\Delta(D|C). \]
As $\Delta(D|C) \subset E\Delta(D|C)$, we have
\[ \Delta(E|D)\Delta(D|C) \subset \Delta(E|D)(E\Delta(D|C)). \]
Now let $x \in \Delta(E|D)$ and $y \in E\Delta(D|C)$. Then $y = \sum_{i=1}^{n} a_i b_i$, with $a_i \in E$ and $b_i \in \Delta(D|C)$, so
\[ xy = \sum_{i=1}^{n} a_i b_i = \sum_{i=1}^{n} (a_i x) b_i \in \Delta(E|D)\Delta(D|C), \]
because $\Delta(E|D)$ is an ideal in $E$. It follows that
\[ \Delta(E|D)(E\Delta(D|C)) \subset \Delta(E|D)\Delta(D|C), \]
and hence the required equality. 

\[ 221 \]
15.3 Rings of fractions

We now consider rings of fractions. Let $C$ be a Dedekind domain, with field of fractions $K$, and $L$ a finite separable extension of $K$. We suppose that $D$ is the integral closure of $C$ in $L$ and $U$ a multiplicative subset of $C$. As $C \subset D$, $U$ is also a multiplicative subset of $D$. We recall that $D' = U^{-1}D$ is the integral closure of $C' = U^{-1}C$ in $L$. (Proposition 12.20).

If $P$ is a prime ideal of $C$ and $U = C \setminus P$, then we write $\Delta_P(L|K)$ for $\Delta(D'|C')$. The different $\Delta_P(L|K)$ is called the different of $L|K$ over $P$.

We now consider the special case of number fields. We wish to find a relation between $\Delta_{L/K}$ and $\Delta(D'|C')$.

**Theorem 15.2** Let $K \subset L$ be number fields, where $L$ is a finite extension of $K$ and $C = O_K$, $D = O_L$ the corresponding number rings. If $U$ is a multiplicative subset of $C$ and $C' = U^{-1}C$, $D' = U^{-1}D$, then

$$D' \Delta_{L/K} = \Delta(D'|C').$$

**Proof** If $x \in D' \Delta_{L/K}$, then $x$ is a finite sum of products of the form $ab$, with $a \in D'$ and $b \in \Delta_{L/K}$. However, $a = \frac{a'}{u}$, with $d \in D$ and $u \in U$. As $\Delta_{L/K}$ is an ideal in $D$, $db \in \Delta_{L/K}$, so $x = \frac{x'}{u}$, with $y \in \Delta_{L/K}$ and $u \in U$.

Let $z \in D'^*$; then $T_{L/K}(zD') \subset C'$. As $D$ is a finitely generated $\mathbb{Z}$-module, $D$ is a finitely generated $C$-module. Let $\{t_1, \ldots, t_m\}$ be a generating set of $D$. Then $T_{L/K}(zt_i) = \frac{zt_i}{u_i}$, with $c_i \in C$ and $u_i \in U$. We set $u_0 = u_1 \cdots u_m \in U$. Then

$$T_{L/K}(zu_0t_i) = u_0T_{L/K}(zt_i) \in C,$$

for $i = 1, \ldots, m$. Hence

$$T_{L/K}(zu_0D) \subset C \implies zu_0 \in D^*.$$  

Now, $\Delta(D|C) = D^{*-1}$ and $y \in \Delta(D|C)$, so, by Proposition 12.8, $yzu_0 \in D$. From this we deduce that

$$xz = \frac{yzu_0}{u_0} \in D'.$$

Thus, for every $z \in D'^*$, $xz \in D'$. Using Proposition 12.8 again, we obtain that $x$ belongs to the inverse of $D'^*$, i.e., $x \in \Delta(D'|C')$. We have shown that $D' \Delta_{L/K} \subset \Delta(D'|C')$.

We now consider the reverse inclusion. Let $x \in \Delta(D'|C')$. First we recall that $D^*$ is a fractional ideal of $D$ (Proposition 15.3), hence $D^*$ is a finitely generated $D$-module (Proposition 12.7). Let $\{z_1, \ldots, z_n\}$ be a generating set of the $D$-module $D^*$. Then $T_{L/K}(z_iD) \subset C$. If $\frac{y}{u} \in D'$, then

$$T_{L/K}(z_iy) = \frac{1}{u}T_{L/K}(zu_0) \in C' \implies T_{L/K}(z_iD') \subset C',$$

which implies that $z_i \in D'^*$. Using Proposition 12.8, we obtain $xz_i \in C' \subset D' = U^{-1}D$ and so we may write $xz_i = \frac{d_i}{u_i}$, with $d_i \in D$ and $u_i \in U$. Let $u_0 = u_1 \cdots u_n \in U$. Then $u_0xz_i \in D$, for $i = 1, \ldots, n$, hence $u_0xD^* \subset D$, thus

$$ux \Delta(D|C)^{-1} \subset D \implies ux \in D \Delta(D|C) = \Delta(D|C)$$

and so

$$x \in U^{-1} \Delta(D|C) \subset D' \Delta(D|C).$$

Therefore

$$\Delta(D'|C') \subset D' \Delta(D|C).$$

This ends the proof.
15.4 Preliminary work for Dedekind’s different theorem

Let $K \subset L$ be number fields with respective associated number rings $C$ and $D$. The different $\Delta_{L/K}$ is an ideal in $D$ such that $\Delta_{L/K} \neq \{0\}$. If $\Delta_{L/K} \neq D$, then there exist nonzero prime ideals $Q_1, \ldots, Q_r$ in $D$ and positive integers $n_1, \ldots, n_r$ such that

$$\Delta_{L/K} = Q_1^{n_1} \cdots Q_r^{n_r}.$$ 

If $Q$ belongs to the set of prime ideals in this decomposition and $Q = Q_i$, then we set $s_Q = s_{Q_i}(L/K) = n_i$. For any other prime ideal $Q$ in $D$, we set $s_Q = 0$. In particular, if $\Delta_{L/K} = D$, then $s_Q = 0$, for all nonzero prime ideals in $D$. $s_Q$ is called the exponent at $Q$ of the different $\Delta_{L/K}$.

If $Q$ is a nonzero prime ideal in $D$, then $P = C \cap Q$ is a nonzero prime ideal in $C$ (Theorem 13.1). From Proposition 13.1 we have $Q|DP$. If

$$DP = Q_1^{e_1} \cdots Q_r^{e_r},$$

then $Q = Q_i$, for some $Q_i$ in the decomposition of $DP$. We call $e_i$ the ramification index of $Q$ and note it $e_Q$. (In fact, $e_Q = e(Q|P)$, where $P = C \cap Q$.) $Q$ is said to be ramified if $e_Q \geq 2$. There is an important relation between $s_Q$ and $e_Q$:

**Result** For every nonzero prime ideal $Q$ in $D$, we have $s_Q \geq e_Q - 1$. In addition, $s_Q = e_Q - 1$ if and only if the characteristic of the field $D/Q$ does not divide $e_Q$.

The proof of this result is rather long and requires some preliminary work. This we will do in this section and in the next we will concentrate our attention on the proof of the result.

**Lemma 15.3** Let $\psi : S \longrightarrow \tilde{S}$ be a surjective ring homomorphism. We suppose that $R$ is a subring of $S$ such that $S$ is a free $R$-module with basis $B = \{x_1, \ldots, x_n\}$. We note $\tilde{R}$ the image of $R$ and $\tilde{B} = \{\tilde{x}_1, \ldots, \tilde{x}_n\}$ the image of $B$ and we suppose that $\tilde{S}$ is a free $R$-module with basis $\tilde{B}$. If $x \in S$, then

$$\psi \left( N_{S/R}(x) \right) = N_{\tilde{S}/\tilde{R}}(\tilde{x}),$$

$$\psi \left( T_{S/R}(x) \right) = T_{\tilde{S}/\tilde{R}}(\tilde{x}),$$

$$\psi^* \left( \text{char} \ S/R \right) = \text{char} \ S/\tilde{R} \tilde{x},$$

where $\psi^*$ is the mapping from $S[X]$ into $\tilde{S}[X]$ which applies $\psi$ to each coefficient of a polynomial of $S[x]$.

**Proof** We note $\theta_2$, the mapping from $S$ into itself defined by multiplication by $x$ and $M(\theta_2)$ the matrix of $\theta_2$ in the basis $B$. In the same way we note $\theta_3$ the mapping from $\tilde{S}$ into itself defined by multiplication by $\tilde{x}$ and $M(\theta_3)$ the matrix of $\theta_3$ in the basis $\tilde{B}$. If

$$xx_j = \sum_{i=1}^{n} r_{ij} x_i \quad j = 1, \ldots, n,$$

then

$$\tilde{x}\tilde{x}_j = \sum_{i=1}^{n} \tilde{r}_{ij} \tilde{x}_i \quad j = 1, \ldots, n.$$
Therefore,
\[ M(\theta_x) = (r_{ij}) \quad \text{and} \quad M(\theta_\ast) = (\bar{r}_{ij}). \]

If we apply \( \psi \) to the coefficients of the characteristic polynomial \( \text{char } s_{/R}(x) = \det (XI - M(\theta_x)) \), then we obtain \( \det (XI - M(\theta_\ast)) = \text{char } s_{/R}(\bar{x}) \), i.e., the third relation. The other two relations follow easily.

The next preliminary results are more difficult. Let \( R \) be a ring and \( K \) a subfield of \( R \). Then \( R \) is a \( K \)-vector space. We suppose that \( \dim_K R = n < \infty \). In addition, let \( \theta : R \to R \) be a \( K \)-linear endomorphism and we suppose the existence of \( K \)-subspaces \( R_i \) of \( R \) forming a decreasing sequence

\[ R = R_0 \supset R_1 \supset \cdots \supset R_{k-1} \supset R_k = \{0\} \]

such that \( \theta(R_i) \subset R_i \), for \( i = 1, \ldots, k \). Then \( \theta \) induces a \( K \)-linear endomorphism \( \theta_i \) on \( R_{i-1}/R_i \) defined by

\[ \theta_i(x + R_i) = \theta(x) + R_i. \]

(If \( x' \in R_i \), then
\[ \theta(x + x') + R_i = \theta(x) + \theta(x') + R_i = \theta(x) + R_i, \]

because \( \theta(x') \in R_i \), so \( \theta_i \) is well-defined.)

**Lemma 15.4** For each index \( i = 1, \ldots, k \), let \( B_i = \{x_{i1}, \ldots, x_{im_i}\} \) be a set of elements of \( R_{i-1} \) such that \( \{x_{i1} + R_i, \ldots, x_{im_i} + R_i\} \) is a basis of \( R_{i-1}/R_i \). Then, for \( i = 1, \ldots, k \), the set

\[ B_i = B_1 \cup \cdots \cup B_k \]

is a basis of \( R_{i-1} \). In particular,

\[ B = \bar{B}_1 = B_1 \cup \cdots \cup B_k \]

is a basis of \( R \).

**Proof** If \( x \in R_{i-1} \), then there exist \( \lambda_{i1}, \ldots, \lambda_{im_i} \in K \) and \( y \in R_i \) such that

\[ x = \lambda_{i1}x_{i1} + \cdots + \lambda_{im_i}x_{im_i} + y. \]

As \( y \in R_i \), there exist \( \lambda_{i+1,1}, \ldots, \lambda_{i+1,m_{i+1}} \in K \) and \( z \in R_{i+1} \) such that

\[ y = \lambda_{i+1,1}x_{i+1,1} + \cdots + \lambda_{i+1,m_{i+1}}x_{i+1,m_{i+1}} + z. \]

Continuing in the same way, we see that \( \bar{B}_i \) is a generating set of \( R_{i-1} \), since \( R_k = \{0\} \).

Suppose that

\[ \lambda_{i1}x_{i1} + \cdots + \lambda_{im_i}x_{im_i} + \lambda_{i+1,1}x_{i+1,1} + \cdots + \lambda_{i+1,m_{i+1}}x_{i+1,m_{i+1}} + \cdots + \lambda_{km_k}x_{km_k} = 0. \]

Then

\[ \lambda_{i+1,1}x_{i+1,1} + \cdots + \lambda_{km_k}x_{km_k} \in R_i \implies \lambda_{i1}x_{i1} + \cdots + \lambda_{im_i}x_{im_i} \in R_i. \]

As \( \{x_{i1} + R_i, \ldots, x_{im_i} + R_i\} \) is a basis of \( R_{i-1} \), we have \( \lambda_{i1} = \cdots = \lambda_{im_i} = 0 \) and it follows that \( \lambda_{i+1,1}x_{i+1,1} + \cdots + \lambda_{km_k}x_{km_k} = 0 \). We now repeat the preceding argument to show that \( \lambda_{i+1,1} = \cdots = \lambda_{i+1,m_{i+1}} = 0 \). Continuing in the same way we find that all the coefficients \( \lambda_{ij} \) have the value 0. Hence \( \bar{B}_i \) is an independent set and so a basis of \( R_{i-1} \).

The basis \( B \) enables us to find a factorization of the characteristic polynomial of the \( K \)-linear homomorphism \( \theta \) defined above.
Proposition 15.5 We have

\[ \text{char}_{R/K}(\theta) = \prod_{i=1}^{k} \text{char}_{(R_{i-1}/R_i)/K}(\theta_i). \]

PROOF We consider \( \theta \) with respect to the basis \( \mathcal{B} \). As \( \theta(x_{ij}) \in R_{i-1} \), we may express it in terms of the basis \( \mathcal{B}_i \):

\[ \theta(x_{ij}) = \sum_{l=1}^{m_i} \lambda_{ijkl} x_{il} + \sum_{l=1}^{m_i+1} \lambda_{i+1,jl} x_{i+1,l} + \cdots + \sum_{l=1}^{m_k} \lambda_{kjl} x_{kl}, \]

where the coefficients \( \lambda_{abc} \) belong to \( K \). Then

\[ \theta_i(\bar{x}_{ij}) = \sum_{l=1}^{m_i} \lambda_{ijkl} \bar{x}_{il}, \]

and so

\[ M(\theta) = \begin{pmatrix} M(\theta_1) & 0 & \cdots & 0 \\ M_21 & M(\theta_2) & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ M_k1 & M_{k2} & \cdots & M(\theta_k) \end{pmatrix}, \]

where \( M(\theta) \) is the matrix of \( \theta \) in the basis \( \mathcal{B} \) and, for \( i = 1, \ldots, k \), \( M(\theta_i) \) is the matrix of \( \theta_i \) in the basis \( \mathcal{B}_i = \{ \bar{x}_{i1}, \ldots, \bar{x}_{im_i} \} \) of \( R_{i-1}/R_i \); the other blocks \( M_{ij} \) are matrices with entries in \( K \).

It now follows easily that

\[ \text{char}_{R/K}(\theta) = \prod_{i=1}^{k} \text{char}_{(R_{i-1}/R_i)/K}(\theta_i). \]

This ends the proof. \( \square \)

Suppose now that we remain in the same context and add the following conditions (C):

- a. Each \( R_i \) is an ideal in \( R \);
- b. For each \( i = 1, \ldots, k \), there is no ideal \( I \) in \( R \) such that \( R_{i-1} \nsubseteq I \nsubseteq R_i \);
- c. If \( y \in R_1 \) and \( z \in R_{i-1} \), then \( yz \in R_i \).

Lemma 15.5 Under the conditions (C), if \( y, z \in R \) with \( yz \in R_i \) and \( y \notin R_i \), then \( z \in R_1 \).

PROOF From a. and b. \( R_1 \) is a maximal ideal in \( R \). We claim that \( R_1 \) is the unique maximal ideal. Suppose that \( t \in R_1 \); then \( t \in R_{2-1} \), so, from c., \( t^2 \in R_2 \). Now \( t \in R_1 \) and \( t^2 \in R_{3-1} \), so \( t^3 \in R_3 \). Continuing in the same way, we find that \( t^k \in R_k = \{0\} \), so

\[ (1-t)(1+t+\cdots+t^{k-1}) = 1-t^k = 1, \]

so \( 1-t \) is invertible. If \( I \) is a maximal ideal of \( R \) such that \( I \) is not included in \( R_1 \), then \( R = R_1 + I \), because \( I \) is a maximal ideal in \( R \), so there exist \( t \in R_1 \) and \( u \in I \) such that \( 1 = t + u \). However, \( u = 1-t \) is invertible, which is impossible, because \( I \) is a proper ideal in \( R \). It follows that any maximal ideal \( I \) in \( R \) is included in \( R_1 \) and so \( R_1 \) is the unique maximal ideal of \( R \).
Suppose that \( z \in R \setminus R_1 \) and \( z \) is not invertible. Then \( z \) lies in a maximal ideal \( I \). As there is only one such ideal, namely \( R_1 \), \( z \in R_1 \), a contradiction, so \( z \) is invertible.

Let \( y, z \in R \), with \( yz \in R_i \). If \( z \notin R_1 \), then \( z \) is invertible. Since \( R_i \) is an ideal, we have \( y = z^{-1}yz \in R_i \). \( \Box \)

We are now in a position to establish a key result of this section. We will remain in the same context, with the conditions (C) and suppose that the linear mapping \( \theta = \theta_z \) (multiplication by some fixed \( x \in R \), for some fixed \( x \in R \)).

**Theorem 15.3** For \( i = 1, \ldots, k \),

\[
\text{char}(R_{i-1}/R_i/K) = \text{char}(R/R_i/K) \theta_i,
\]

Hence

\[
\text{char}(R/K(x)) = \left( \text{char}(R/R_i/K) \theta_i \right)^k.
\]

**Proof** We claim that, for \( i = 1, \ldots, k \), there exists a linear isomorphism \( \lambda_i : R_{i-1}/R_i \rightarrow R/R_i \) such that \( \theta_i \circ \lambda_i = \lambda_i \circ \theta_1 \). Let \( u \in R_{i-1} \setminus R_i \). Then \( R_i \subset R_i + Ru \subset R_{i-1} \). As \( R_i \) is an ideal of \( R \) (condition (C) a.), \( R_i + Ru \) is also an ideal of \( R \). In addition, \( R_i + Ru = R_{i-1} \) (condition (C) b.). If \( y + R_i \in R_{i-1}/R_i \), then \( y = y_2 + y_1u \), with \( y_2 \in R_i \) and \( y_1 \in R \). We set

\[
\lambda_i(y + R_i) = y_1 + R_i.
\]

Suppose that \( y = z_2 + z_1u \), with \( z_2 \in R_i \) and \( z_1 \in R \), then

\[
0 = (y_2 - z_2) + (y_1 - z_1)u \implies (y_1 - z_1)u \in R_i.
\]

Given that \( u \notin R_i \), from Lemma 15.5 we obtain that \( y_1 - z_1 \in R_1 \), so \( y_1 + R_i = z_1 + R_1 \), i.e., \( \lambda_i \) is well-defined. Clearly \( \lambda_i \) is a surjective \( R \)-module homomorphism. Suppose that \( \lambda_i(y + R_i) = 0 \in R/R_i \). If \( y = y_2 + y_1u \), then \( y_1 \in R_1 \) and, from condition (C) c., \( y_1u \in R_i \) and so \( y \in R_i \), i.e., \( y = 0 \in R_{i-1}/R_i \). It follows that \( \lambda_i \) is injective. We have shown that \( \lambda_i \) is an isomorphism.

It remains to show that \( \theta_1 \circ \lambda_i = \lambda_i \circ \theta_1 \). Let \( y \) be an element of \( R_{i-1} \) such that \( y = y_2 + y_1u \), with \( y_2 \in R_i \) and \( y_1 \in R \). Then \( xy = xy_2 + (xy_1)u \), with \( xy_2 \in R_i \) and \( xy_1 \in R \). We have

\[
\theta_1(\lambda_i(y + R_i)) = \theta_1(y_1 + R_i) = \theta(y_1) + R_i = xy_1 + R_i,
\]

and then

\[
x y_1 + R_i = \lambda_i(xy + R_i) = \lambda_i(\theta(y) + R_i) = \lambda_i(\theta_i(y + R_i)).
\]

Hence \( \theta_1 \circ \lambda_i = \lambda_i \circ \theta_1 \), as claimed.

Let \( \mathcal{B}_i = \{x_1, \ldots, x_m\} \) be a \( K \)-basis of \( R_{i-1}/R_i \) and \( \mathcal{B}_i' = \{x'_1, \ldots, x'_m\} \), where \( x'_k = \lambda_i(x_k) \), for \( k = 1, \ldots, m \). Then \( \mathcal{B}_i' \) is a \( K \)-basis of \( R/R_i \), because \( \lambda_i \) is a linear isomorphism. If \( \theta_i(x_j) = \sum_{k=1}^m a_{kj} x_k \), then

\[
\lambda_i(\theta_i(x_j)) = \sum_{k=1}^m a_{kj} \lambda_i(x_k) = \sum_{k=1}^m a_{kj} x'_k
\]

and

\[
\theta_1(x'_k) = \theta_1(\lambda_i(x_k)) = \lambda_i(\theta_i(x_j)) = \sum_{k=1}^m a_{kj} x'_k.
\]

Thus the matrix of \( \theta_1 \) with respect to the basis \( \mathcal{B}_i \) and the matrix of \( \theta_1 \) with respect to the basis \( \mathcal{B}_i' \) are the same. It follows that

\[
\text{char}(R_{i-1}/R_i/K) (\theta_i) = \text{char}(R/R_i/K) (\theta_1).
\]

226
and, using Proposition 15.5, we obtain
\[ \text{char } R/K(\theta) = \left( \text{char } (R/R_1)/K(\theta_1) \right)^k, \]
as required, since \( \theta = \theta_x \), the multiplication by \( x \).

We now turn to Dedekind domains. Let \( C \) be a Dedekind domain, with field of fractions \( K \), and \( L \) a separable extension of degree \( n \) of \( K \). We suppose that \( D \) is the integral closure of \( C \) in \( L \). (We know from the remark after Theorem 12.15 that \( D \) is a Dedekind domain, which is distinct from \( C \), if \( n > 1 \).) We take a nonzero prime ideal \( P \) of \( C \). As \( DP \neq \{0\}, D \), we have a decomposition
\[ DP = \prod_{i=1}^{r} Q_i^{e_i}, \]
where the \( Q_i \) are prime ideals in \( D \) and the \( e_i \) positive integers. From Theorem 12.16, \( D/DP \) is a vector space over the field \( C/P = F \) of dimension \( n \). We now define certain canonical mappings:
\[ \psi : C \rightarrow F, \quad \psi_0 : D \rightarrow D/DP \quad \text{and} \quad \psi_i : D \rightarrow D/Q_i = L_i, \]
for \( i = 1, \ldots, r \). It will be shown during the proof of Theorem 15.4 that \( L_i \) is a field extension of \( F \) of finite degree. If \( i \neq j \), then \( Q_i \) and \( Q_j \) are coprime and this is also the case for \( Q_i^{e_i} \) and \( Q_j^{e_j} \). With
\[ U = C \setminus P, \quad C' = U^{-1} C, \quad D' = U^{-1} D \quad \text{and} \quad P' = C' P, \]
we define the following canonical mappings:
\[ \tilde{\psi} : C' \rightarrow C'/P' = F' \quad \text{and} \quad \tilde{\psi}_0 : D' \rightarrow D'/D'P. \]
From Corollary 12.11, there is a ring isomorphism \( \phi \) from \( D/DP \) onto \( D'/D'P \), taking \( d + DP \) to \( \frac{d}{d} + D'P \). The image of \( F \) is \( F' \).

From Proposition 12.4, we have
\[ \cap_{i=1}^{r} Q_i^{e_i} = \prod_{i=1}^{r} Q_i^{e_i} = DP, \]
so, using Corollary F.1, we obtain
\[ D/DP \cong \prod_{i=1}^{r} D/Q_i^{e_i}. \]
Explicitly the isomorphism is defined by
\[ \pi(y + DP) = (y + Q_1^{e_1}, \ldots, y + Q_r^{e_r}). \]
For \( i = 1, \ldots, r \), we define
\[ \pi_i(y + DP) = y + Q_i^{e_i}, \]
i.e., \( \pi_i \) is the projection of \( D/DP \) onto \( D/Q_i^{e_i} \).

If \( A \) and \( B \) are rings and \( \alpha : A \rightarrow B \) a ring homomorphism, then we define \( \alpha^* \) to be the mapping from \( A[X] \) into \( B[X] \) which applies \( \alpha \) to each coefficient of a polynomial in \( A[X] \).

With this preliminary work, we may now state (and prove) the second key result of this section.
Theorem 15.4 If \( x \in D \), then \( \text{char}_{L/K}(x) \in C[X] \) and

- \( \psi^* \left( \text{char}_{L/K}(x) \right) = \prod_{j=1}^{r} \text{char}_{L/F} \left( \psi_j(x) \right)^{x_j}; \)
- \( \psi \left( T_{L/K}(x) \right) = \sum_{j=1}^{r} c_j T_{L/F} \left( \psi_j(x) \right); \)
- \( \psi \left( N_{L/K}(x) \right) = \prod_{j=1}^{r} N_{L/F} \left( \psi_j(x) \right)^{x_j}. \)

(\text{It is important to show that char}_{L/K}(x) \in C[X], because the mapping } \psi \text{ is defined on } C.\)

**Proof** The proof of this result is rather long, so we have divided it into parts and paragraphs. Also, to simplify the notation, in general we write \( x \) for \( \frac{1}{x}. \)

**Part 1**

Using the proof of Theorem 12.17, we note certain properties of \( C' \) and \( D' \), namely \( C' \) is a PID, \( D' \) is the integral closure of \( C' \) in \( L \) and \( D' \) is a free \( C' \)-module of rank \( n \). In addition, \( D'/D'P \) is an \( F' \)-vector space of rank \( n \); if \( B' = \{ x_{d_1}', \ldots, x_{d_p}' \} \) is a basis of the free \( C' \)-module \( D' \), then \( B' = \{ \bar{x}_i' \} \) is a basis of the \( F' \)-vector space \( D'/D'P \), where \( \bar{x}_i' \) is the image \( x_i' \) under the canonical mapping \( \bar{\psi}_0 \) of \( D' \) onto \( D'/D'P \).

Now let \( V = C' \setminus \{ 0 \} \). The set \( V \) is a multiplicative subset of the integral domain \( C' \) and \( V^{-1}C' \) is the field of fractions of \( C' \), which is \( K \). Also, \( D' \) is the integral closure of \( C' \) in \( L \), so, by Proposition 12.20, \( V^{-1}D' \) is the integral closure of \( V^{-1}C' \) in \( L \), i.e., the integral closure of \( K \) in \( L \). If \( \gamma \) is the canonical monomorphism from \( D' \) into \( V^{-1}D' \), then from Section 12.8 we have

\[
\text{char}_{V^{-1}D'/V^{-1}C'}(\gamma(x)) = \gamma^*(\text{char}_{D'/C'}(x)).
\]

As \( \gamma \) is the canonical inclusion of \( D' \) in \( V^{-1}D' \), we may identify \( D' \) with its image under \( \gamma \) and so we obtain

\[
\text{char}_{L/K}(x) = \text{char}_{V^{-1}D'/V^{-1}C'}(x) = \text{char}_{D'/C'}(x).
\]

We aim to study \( \text{char}_{D'/C'}(x) \). At the beginning of the proof we recalled certain properties of \( C' \) and \( D' \), which permit us to apply Lemma 15.3 with \( \bar{\psi}_0 \) in the place of \( \psi \). We obtain

\[
\bar{\psi}_0^* \left( \text{char}_{D'/C'}(x) \right) = \text{char}_{(D'/D'P)/F'} \left( \bar{\psi}_0(x) \right).
\]

From Corollary 12.11, there is a ring isomorphism \( \phi \) from \( D/DP \) onto \( D'/D'P \), taking \( d + DP \) to \( d + D'P \). The image of \( F \) is \( F' \). We now show that

\[
\text{char}_{(D'/D'P)/F'} \left( \bar{\psi}_0(x) \right) = \phi^* \left( \text{char}_{(D/DP)/F} \left( \psi_0(x) \right) \right).
\]

If \( B = \{ d_1 + DP, \ldots, d_n + DP \} \) is a basis of the \( F \)-vector space \( D/DP \), then \( B' = \{ d_1 + D'P, \ldots, d_n + D'P \} \) is a basis of the \( F' \)-vector space \( D'/D'P \). Also, if \( x \in D \), then \( \psi_0(x) = x + DP \) and \( \bar{\psi}_0(x) = x + D'P \). We consider the matrices of \( \theta_{\bar{\psi}_0}(x) \) and \( \theta_{\psi_0}(x) \) in the respective bases \( B \) and \( B' \). If

\[
\psi_0(x)(d_k + DP) = \sum_{i=1}^{n} (a_{ik} + P)(d_i + DP) = \sum_{i=1}^{n} (a_{ik} + DP)(d_i + DP),
\]
then
\[
\phi(\psi_0(x))\phi(d_k + DP) = \sum_{i=1}^{n} \phi(a_{ik} + DP)\phi(d_i + DP) = \sum_{i=1}^{n} (a_{ik} + D'P)(d_i + D'P) = \sum_{i=1}^{n} (a_{ik} + C'P)(d_i + D'P).
\]

However,
\[
\phi(\psi_0(x)) = \psi_0(x) + D'P = \phi \circ \psi(x) = \tilde{\psi}_0(x),
\]
hence
\[
\tilde{\psi}_0(x)(d_k + D'P) = \sum_{i=1}^{n} (a_{ik} + C'P)(d_i + D'P).
\]

If \((a_{ik})\) is the matrix of \(\theta_{\psi_0(x)}\) in the basis \(B\), then the matrix of \(\theta_{\tilde{\psi}_0(x)}\) in the basis \(B'\) has the form \((\phi(a_{ik}))\). From this we obtain
\[
\text{char}_{(D'/DP)/F'}(\tilde{\psi}_0(x)) = \phi^*(\text{char}_{(D/DP)/F}(\psi_0(x)));
\]
as required.

- To sum up, we have shown that
\[
\tilde{\psi}_0^*(\text{char}_{D'/C'}(x)) = \phi^*(\text{char}_{(D/DP)/F}(\psi_0(x)));
\]
This finishes the first part of the proof.

**Part 2**

- Our first step in this part is to show that
\[
\text{char}_{(D/DP)/F}(\psi_0(x)) = \text{char}_{\prod_{i=1}^{r} D/Q^*_i/F}(\pi(\psi_0(x))).
\]
- The ring isomorphism \(\pi : D/DP \to \prod_{i=1}^{r} D/Q^*_i\), enables us to define a scalar multiplication on \(\prod_{i=1}^{r} D/Q^*_i\), making it into an \(F\)-vector space:
\[
(c + P) \cdot \pi(D + DP) = \pi(c + DP)\pi(d + DP) = \pi(c + DP)(d + DP).
\]
Then
\[
\pi((c + P) \cdot (D + DP)) = \pi(c + DP)(d + DP) = (c + P) \cdot \pi(D + DP),
\]
and so \(\pi\) is an \(F\)-linear isomorphism.

- With the notation already used, we define \(\theta_{\psi_0(x)}\) to be multiplication by \(\psi_0(x)\) in \(D/DP\) and \(\theta_{\pi(\psi_0(x))}\) to be multiplication by \(\pi(\psi_0(x))\) in \(\prod_{i=1}^{r} D/Q^*_i\). We claim that
\[
\pi \circ \theta_{\psi_0(x)} \circ \pi^{-1} = \theta_{\pi(\psi_0(x))}.
\] (15.4)
Using the fact that $\pi$ is a ring homomorphism, we have

$$\pi \circ \theta_{\psi_0(x)}(d + DP) = \pi(\psi_0(x)(d + DP)) = \pi(\psi_0(x))\pi(d + DP) = \theta_{\pi(\psi_0(x))} \circ \pi(d + DP),$$

hence the claim.

- If $B = \{x_1, \ldots, x_n\}$ is a basis of $D/DP$, then $B' = \{x'_1, \ldots, x'_n\}$ is a basis of $\prod_{i=1}^r D/Q^e_i$.

For $x' \in B'$ there exist $a_{ik} \in F$, with $i = 1, \ldots, n$, such that

$$\pi(\psi_0(x))x'_k = \sum_{i=1}^n a_{ik}x'_i = \sum_{i=1}^n a_{ik} \pi(x_i) = \pi \sum_{i=1}^n a_{ik}x_i,$$

where we have used the linearity of $\pi$. Employing equation (15.4), we obtain

$$\pi(\psi_0(x))x'_k = \theta_{\pi(\psi_0(x))}(x'_k) = \pi \circ \theta_{\psi_0(x)} \circ \pi^{-1}(x'_k) = \pi \circ \theta_{\psi_0(x)}(x_k) = \pi(\psi_0(x)x_k).$$

Therefore

$$\pi(\psi_0(x)x_k) = \pi \sum_{i=1}^n a_{ik}x_i = \psi_0(x)x_k.$$

Thus the matrix of $\theta_{\psi_0(x)}$ in the basis $B$ is the same as that of $\theta_{\pi(\psi_0(x))}$ in the basis $B'$. From this we conclude that

$$\text{char}_{(D/DP)/F}(\psi_0(x)) = \text{char}_{\prod_{i=1}^r(D/Q^e_i)/F}(\pi(\psi_0(x))),$$

as required.

- We now show that

$$\text{char}_{\prod_{i=1}^r(D/Q^e_i)/F}(\pi(\psi_0(x))) = \text{char}_{\prod_{i=1}^r(D/Q^e_i)/F}(\pi(\psi_0(x))).$$

We now use Theorem 15.3. Let

$$R = \prod_{i=1}^r D/Q^e_i, R_1 = \prod_{i=2}^r D/Q^e_i, R_2 = \prod_{i=3}^r D/Q^e_i, \ldots, R_r = \{0\}.$$

Then

$$R \supset R_1 \supset R_2 \supset \cdots \supset R_r = \{0\},$$

and the $R_i$ are $F$-linear subspaces. Considering the explicit form of the mapping $\pi$ we deduce that $\theta_{\pi(\psi_0(x))}(R_i) \subset R_i$. In addition, we have $R_{i-1}/R_i \simeq D/Q^e_i$. The linear endomorphism $\theta_i$ induced on $R_{i-1}/R_i$ by $\theta_{\pi(\psi_0(x))}$ is the multiplication by $\pi_i(\psi_0(x))$ in $D/Q^e_i$. Using Proposition 15.5, we obtain

$$\text{char}_{\prod_{i=1}^r(D/Q^e_i)/F}(\pi(\psi_0(x))) = \prod_{i=1}^r \text{char}_{(D/Q^e_i)/F}(\pi_i(\psi_0(x))).$$

This ends the second part of the proof.
Part 3

- Our aim in this section is to determine the polynomials in the product on the right hand side of equation (15.5), namely, for \( i = 1, \ldots, r \), to show that

\[
\text{char } (D/Q_j^{e_i})/F \left( \pi_i(x) \right) = \text{char } L_i/F (x).
\]

We apply Theorem 15.3 for a given \( j \) and set \( k = e_j \). To apply the theorem, we define

\[
R = D/Q_j^k \quad \text{and} \quad R_1 = Q_j/Q_j^1, \ldots, R_{k-1} = Q_j^{k-1}/Q_j^k, R_k = Q_j^k/Q_j^k = \{0\}.
\]

Then \( R \) is a ring. We notice that \( P \subset DP \subset Q_j^k \), so the mapping

\[
\delta : F \longrightarrow R, c + P \longmapsto c + Q_j^k
\]

is a well-defined ring homomorphism. If \( \delta(c + P) = 0 \), then \( c \in C \cap Q_j^k \). However,

\[
P \subset C, P \subset Q_j^k \implies P \subset C \cap Q_j^k \quad \text{and} \quad C \cap Q_j^k \subset C \cap Q_j = P,
\]

so \( C \cap Q_j^k = P \) and it follows that \( \delta \) is a monomorphism. Hence we may define an \( F \)-vector space structure on \( R \). In fact, \( R \) is finite-dimensional. To see this, we notice that \( D/DP \) is an \( n \)-dimensional \( F \)-vector space and that \( Q_j^k/DP \) is a vector subspace of \( D/DP \). Given that

\[
(D/DP)/(Q_j^k/DP) \cong D/Q_j^k = R,
\]

\( R \) is finite-dimensional. We also need to show that the \( R_i \) are vector subspaces of \( R \). For \( i = 1, \ldots, k-1 \), the set \( R_i \) is clearly an additive group. If \( c \in C \) and \( x \in Q_j^k \), then \( cx \in Q_j^k \), because \( c \in D \) and \( Q_j^k \) is an ideal of \( D \). Therefore we may define a scalar product on \( R_i \) by \( (c+P)(x+Q_j^k) = cx + Q_j^k \). (There is no difficulty in seeing that this scalar product is well-defined.) Hence the \( R_i \) are \( F \)-vector spaces. Clearly

\[
R \supset R_1 \supset \cdots \supset R_{k-1} \supset R_k = \{0\},
\]

so the \( R_i \) are finite-dimensional subspaces of \( R \).

- In order to apply Theorem 15.3 we need to check that the conditions (C) given before Lemma 15.3 are satisfied:

  • a. If \( x + Q_j^k \in R \) and \( y + Q_j^k \in R_i \), then \( (x + Q_j^k)(y + Q_j^k) = xy + Q_j^k \), with \( xy \in Q_j^k \), because \( y \in Q_j^k \), so the \( R_i \) are ideals of \( R \).

  • b. Suppose that there is an ideal \( I \) of \( R \) such that \( R_{i-1} \supset I \supset R_i \). Let \( \lambda : D \longrightarrow D/Q_j^k \) be the standard homomorphism. If \( J = \lambda^{-1}(I) \), then \( J \) is an ideal and \( Q_j^{-1} \supset J \supset Q_j^k \). As \( Q_j^{-1} \supset J \), there is an ideal \( A \) such that \( J = Q_j^{-1}A \). If \( A = D \), then \( J = Q_j^{-1} \). If this is not the case, then, as \( J \supset Q_j^k \), \( A = Q_j \) and so \( J = Q_j^k \). It follows that \( R_{i-1} = I \) or \( I = R_i \).

  • c. If \( \bar{y} = y + Q_j^k \in R_1 \) and \( \bar{z} = z + Q_j^k \in R_{i-1} \); then \( \bar{y}\bar{z} = yz + Q_j^k \), with \( yz \in Q_j^k \), so \( \bar{y}\bar{z} \in R_i \).

Therefore the conditions (C) are satisfied.
We now apply Theorem 15.3. Let \( x \in D \) and \( \bar{x} = x + Q^j \in R \) and consider the mapping \( \theta = \theta_\bar{x} \) defined by multiplication by \( \bar{x} \): for all \( \bar{y} \in R \),

\[
\theta(\bar{y}) = \bar{x} \bar{y} = xy + Q^j.
\]

Since \( R_j \) is an ideal of \( R \), \( \theta(R_j) \subset R_j \). From Theorem 15.3 we have

\[
\text{char } (D/Q^j) / F (\pi_j((\psi_0(x)))) = \text{char } R/F (\pi_j((\psi_0(x)))) = (\text{char } (R/R_1) / F (\theta_1))^k
\]

and for \( \theta_1 \) we have

\[
\theta_1(y + R_1) = \bar{x} \bar{y} + R_1.
\]

- Next we notice that

\[
R/R_1 = (D/Q^j) / (Q_j/Q^j) \cong D/Q_j = L_j.
\]

(As \( R_1 \) is a finite-dimensional subspace of \( R \), \( R/R_1 \) is finite-dimensional and hence this is the case for \( L_j \).) The isomorphism of \( F \)-vector spaces from \( R/R_1 \) onto \( L_j \), which we note \( \alpha \), has the explicit form:

\[
\alpha(y + R_1) = y + Q_j = \psi_j(y).
\]

If \( x \in D \), then the element \( \psi_j(x) \) belongs to \( L_j \) and, in conformity with the notation already used, we define the mapping \( \theta_{\psi_j(x)} \) to be multiplication by the element \( \psi_j(x) \). Then, for all \( y \in D \),

\[
\theta_{\psi_j(x)}(\alpha(y + R_1)) = (x + Q_j)(y + Q_j) = xy + Q_j
\]

and

\[
\alpha(\theta_1(y + R_1)) = \alpha(\bar{x} \bar{y} + R_1) = xy + Q_j,
\]

thus

\[
\theta_{\psi_j(x)} \circ \alpha = \alpha \circ \theta_1.
\]

We may now write

\[
\text{char } (R/R_1) / F (\theta_1) = \text{char } \frac{\alpha^{-1} \circ \theta_{\psi_j(x)} \circ \alpha}{\alpha(\theta_{\psi_j(x)}) / F (\theta_{\psi_j(x)})}
\]

Therefore we have obtained

\[
\text{char } (D/Q^j) / F (\pi_j((\psi_0(x)))) = \text{char } L_j / F (\psi_j(x))^k
\]

and it follows that

\[
\prod_{i=1}^r \text{char } (D/Q^j) / F (\pi_i((\psi_0(x)))) = \prod_{i=1}^r \text{char } L_i / F (\psi_i(x))^c_i.
\]

**Part 4**

We have now shown that

\[
\text{char } (D/D_P) / F (\psi_0(x)) = \prod_{i=1}^r \text{char } L_i / F (\psi_i(x))^c_i.
\]
and so
\[ \tilde{\psi}_0^* (\text{char } D'/C'(x)) = \phi^* \left( \prod_{i=1}^r \text{char } L_i/F (\psi_i(x))^{e_i} \right). \]

However,
\[ \tilde{\psi}_0^* (\text{char } D'/C'(x)) = \phi^* \circ \psi^* (\text{char } L/K(x)) \]
and it follows that
\[ \psi^* (\text{char } L/K(x)) = \prod_{i=1}^r \text{char } L_i/F (\psi_i(x))^{e_i}, \]
which is the first equality in the statement of the theorem.

**Part 5**

Let us set \( n = \deg \text{char } L/K(x) \) and \( n_j = \deg \text{char } L_j/F (\psi_j(x)) \), for \( j = 1, \ldots, r \). The constant term of \( \psi^* (\text{char } L/K(x)) \) is the product of the constant terms of the polynomials \( \text{char } L/F (\psi_j(x)) \), each taken respectively to the power \( e_j \). However, the constant term of \( \psi (\text{char } L/K(x)) \) is \( (-1)^n \psi (N_{L/K}(x)) \) and the constant term of the product of the polynomials \( \text{char } L_j/F (\psi_j(x)) \), each taken respectively to the power \( e_j \), is
\[ (-1)^{\sum_{j=1}^r n_j e_j} \prod_{j=1}^r N_{L_j/F} (\psi_j(x))^{e_j}. \]

As \( n = \sum_{j=1}^r n_j e_j \), we obtain the third equality, namely
\[ \psi (N_{L/K}(x)) = \prod_{j=1}^r (N_{L_j/F} (\psi_j(x)))^{e_j}. \]

For the second equality we consider the coefficients of \( X^{n-1} \) in the two sides of the first equality. The coefficient of \( X^{n-1} \) on the left-hand side is \( -\psi (T_{L/K}(x)) \). The coefficient of \( X^{n-1} \) on the right-hand side is the sum of coefficients of the \( X^{n_i-1} \), each multiplied respectively by \( e_j \). As the coefficient of \( X^{n_i-1} \) is \( -T_{L_i/F} (\psi_j(x)) \), we have the second equality, i.e.,
\[ \psi (T_{L/K}(x)) = \sum_{j=1}^r e_j T_{L_j/F} (\psi_j(x)). \]

This ends the proof. \( \square \)

The theorem we have just proved has an interesting corollary.

**Corollary 15.2** Let \( C \) be a Dedekind domain with fraction field \( K \), \( L \) a finite separable extension of \( K \) and \( D \) the integral closure of \( C \) in \( L \). If \( P \) is a prime ideal of \( C \) and \( DP = \prod_{i=1}^r Q_i^{e_i} \), then
\[ [L : K] = \sum_{i=1}^r e_i f_i, \]
where \( f_i = [D/Q_i : C/P] \).
proof It is sufficient to consider the degrees of the characteristic polynomials in the statement of Theorem 15.4 a. □

Remark The corollary which we have just proved is in fact a generalization of Theorem 13.6.

We will need another result, based on the Chinese remainder theorem.

Proposition 15.6 Let $D$ be a Dedekind domain and $P_1,\ldots,P_s$ distinct nonzero prime ideals in $D$. Suppose that $x_1,\ldots,x_s \in D$ and $e_1,\ldots,e_s \in \mathbb{N}$. Then there exists $x \in D$ such that

\[ x - x_i \in P_i^{e_i} \quad \text{and} \quad x - x_i \notin P_i^{e_i+1}, \]

for $i = 1,\ldots,s$.

proof For each $i$, $P_i^{e_i+1}$ is strictly included in $P_i^{e_i}$, so there exists $a_i \in P_i^{e_i} \setminus P_i^{e_i+1}$. If $i \neq j$, then $P_i^{e_i+1}$ and $P_j^{e_j+1}$ are coprime. From the Chinese remainder theorem (Theorem F.1) there exists $x \in D$ such that

\[ x \equiv (x_1 + a_1) \pmod{P_1^{e_1+1}} \]

\[ \vdots \]

\[ x \equiv (x_s + a_s) \pmod{P_s^{e_s+1}}. \]

Then, for all $i$,

\[ x - (x_i + a_i) \in P_i^{e_i+1} \implies x - x_i \in P_i^{e_i}. \]

If $x - x_i \in P_i^{e_i+1}$, then

\[ (x - x_i) - a_i + a_i \in P_i^{e_i+1} \implies a_i \in P_i^{e_i+1}, \]

a contradiction. This proves the result. □

15.5 Proof of Dedekind’s different theorem

Having done the preliminary work, we may prove the inequality referred to in the last section. For the notation, it is sufficient to look at the beginning of the previous section. We only recall that $K \subset L$ are number fields with associated number rings $C$ and $D$. We set $n = [L : K]$.

Theorem 15.5 For every nonzero prime ideal $Q$ in $D$, we have $s_Q \geq e_Q - 1$. In addition, $s_Q = e_Q - 1$ if and only if the characteristic of the field $D/Q$ does not divide $e_Q$.

proof As the proof is long, we will break it up into three parts, namely

- a. Proof of the inequality;
- b. The case where the characteristic of $D/Q$ divides $e_Q$;
- c. The case where the characteristic of $D/Q$ does not divide $e_Q$. 

234
a. **Proof of the inequality** Let $Q$ be a nonzero prime ideal in $D$ and set $P = Q \cap C$. We now set $U = C \setminus P$, $C' = U^{-1}C$ and $D' = U^{-1}D$. In the decompositions of $\Delta_{L/K}$ and $DP$ appear a finite set of nonzero prime ideals $Q_1, \ldots, Q_m$. We have

$$\Delta_{L/K} = \prod_{i=1}^{m} Q_{i}^{s_{i}} \quad \text{and} \quad DP = \prod_{i=1}^{m} Q_{i}^{e_{i}}.$$  

(Certain $s_i$ or $e_i$ may be equal to 0.) From Proposition 12.16,

$$D'P = \prod_{i=1}^{m} D'Q_{i}^{e_{i}}$$

and, having number fields, from Theorem 15.2,

$$\Delta(D'|C') = D'\Delta_{L/K} = \prod_{i=1}^{m} D'Q_{i}^{s_{i}}.$$  

Hence the complementary module $D'^*$ has the form $\prod_{i=1}^{m} D'Q_{i}^{-s_{i}}$. Then the inequalities

$$s_{i} \geq e_{i} - 1 \quad i = 1, \ldots, m$$

hold if and only if $\prod_{i=1}^{m} D'Q_{i}^{-e_{i}} \subset D'^*$. We aim to show that this is the case.

Let $x \in \prod_{i=1}^{m} D'Q_{i}^{1-e_{i}}$. From Theorem 12.11 we know that $P' = C'P$ is a principal ideal, so there exists $t \in C'$ such that $P' = C't$. We may suppose that $t \in C$. However,

$$\prod_{i=1}^{m} D'Q_{i}^{e_{i}} = D'P = D'C'P = D'P' = D'C't = D't,$$

so $xt \in \prod_{i=1}^{m} D'Q_{i}$. We claim that $T_{L/K}(xt) \in P'$. (As $xt \in D'$, we may consider that $xt \in L$, so $T_{L/K}(xt)$ is defined.) We notice first that $D'$ is a free $C'$-module of rank $n$. This has already been shown in the proof of Theorem 12.17 in a more general framework. We have also seen, in the proof of Theorem 15.4, that if $V = C' \setminus \{0\}$, then $V$ is a multiplicative subset of $C'$, $V^{-1}C' = K$, $V^{-1}D' = L$ and, for $x \in D'$, we have

$$\text{char } L/K(x) = \text{char } V^{-1}D'/V^{-1}C'(x) = \text{char } D'/C'(x).$$

It follows that

$$T_{L/K}(xt) = T_{D'/C'}(xt),$$

because $xt \in D'$.

We now consider $T_{D'/C'}(xt)$. In the proof of Theorem 12.17 we saw that, if $B' = \{x'_1, \ldots, x'_n\}$ is a basis of the free $C'$-module $D'$, then $B' = \{\bar{x}'_1, \ldots, \bar{x}'_n\}$ is a basis of the $C'/C'P$-vector space $D'/D'P$, where $\bar{x}'_i$ is the image of $x'_i$ under the standard mapping of $D'$ onto $D'/D'P$. We can thus apply Lemma 15.3, with $\psi$ this standard mapping, to obtain

$$\overline{T_{D'/C'}(xt)} = T_{(D'/(D'P))(C'/P')}(\overline{xt}).$$

We claim that $\overline{xt}$ is a nilpotent element of the ring $D'/D'P$. Let $r = e_1 + \cdots + e_m$. Then

$$xt \in \prod_{i=1}^{m} D'Q_i \implies xt = y_1 \cdots y_m \quad y_i \in D'Q_i,$$
where \( y_i = d_i q_i \), with \( d_i \in D' \) and \( q_i \in Q_i \). Hence
\[
(x_t')^r = y_1^{e_1} y_2^{e_2} \cdots y_m^{e_m} d_t = d_1^{e_1} q_1^{e_1} \cdots d_m^{e_m} q_m^{e_m} d,
\]
where \( d \in D' \). As \( \prod_{i=1}^m D'Q_i e_i \) is an ideal, \((x_t')^r \in \prod_{i=1}^m D'Q_i e_i = D'P\), which implies that \( \overline{x_t'} \) is a nilpotent element of the ring \( D'/D'P \), as claimed. From the fact that \( \overline{x_t'} \) is a nilpotent element of the ring \( D'/D'P \) we obtain that \( \dim (D'/D'P)/(C'/P)\overline{x_t'} = X^\alpha \), which implies that \( T_{D'/C'}(x_t) = 0 \); this in turn implies that \( T_{D'/C'}(x_t) = 0 \), which means that \( T_{D'/C'}(x_t) \in D'P \). However, \( T_{D'/C'}(x_t) \in C' \), so
\[
T_{L/K}(x_t) = T_{D'/C'}(x_t) \in C'P = P'.
\]
Now,
\[
t_{T_{L/K}}(x_t) = T_{L/K}(x_t) \in P' = C't \implies T_{L/K}(x_t) \in C'.
\]
If \( y \in D' \), then \( xy \in \prod_{i=1}^m D'Q_i e_i \), so, replacing \( x \) by \( xy \), we obtain \( T_{L/K}(xy) \in C' \). Therefore \( x \in D'^* \), which finishes the proof of the first part of the theorem.

b. The case where the characteristic of \( D/Q \) divides \( \epsilon Q \) Suppose that \( Q \) is a prime ideal in \( D \) such that the characteristic of the field \( D/Q \) divides the ramification index \( \epsilon Q \). If \( P = C \cap Q \), then \( P \) is a nonzero prime ideal. Supposing that \( DP = Q_1 e_1 \cdots Q_m e_m \) is the decomposition of \( DP \) into prime ideals, then \( Q = Q_i \), for some \( i \). Without loss of generality, let us suppose that \( Q = Q_1 \). We set
\[
J = D'Q_1^{-e_1} \prod_{i=2}^m D'Q_i^{-s_i}.
\]
If \( J \subset D'^* = \prod_{i=1}^m D'Q_i^{-s_i} \), then
\[
D'Q_1^{-s_1} | D'Q_1^{-e_1} \Rightarrow D'Q_1^{-s_1} \supset D'Q_1^{-e_1} \Rightarrow D'Q_1^{-s_1} \subset D'Q_1^{-e_1},
\]
which implies that \( s_1 \geq e_1 \). We aim to show that \( J \subset D'^* \). Let \( x \in J \). We notice that
\[
J \subset \prod_{i=2}^m D'Q_i^{-s_i} \Rightarrow x \in \prod_{i=2}^m D'Q_i^{-s_i}.
\]
Since \( 1 - e_i \geq -s_i \), for \( i = 2, \ldots, m \), \( \prod_{i=2}^m Q_1^{1-e_i} \supset \prod_{i=2}^m Q_i^{-s_i} \), so \( x \in \prod_{i=2}^m Q_i^{-e_i} \), and, from part a., we may write \( x = \prod_{i=2}^m Q_i^{-e_i} \). Then \( x \in D' \) and \( T_{L/K}(x_t) = T_{D'/C'}(x_t) \in C' \). We now use Theorem 15.4, with \( \psi : C' \rightarrow C'/P' \) and \( \psi_i : D' \rightarrow D'/D'Q_i \), for \( i = 1, \ldots, m \), the standard mappings. Then, setting \( L'_i = D'/D'Q_i \) and \( F' = C'/P' \), we have
\[
\psi (T_{L/K}(x_t)) = \sum_{i=1}^m e_i T_{L'_i/F'} (\psi_i(x_t)) = e_i T_{L'_i/F'} (\psi_i(x_t)),
\]
because \( x_t \in \prod_{i=2}^m D'Q_i = \bigcap_{i=2}^m D'Q_i \).

In addition, \( \psi_i(x_t) \) is in \( D'/D'Q_i \), which is isomorphic to \( D/Q_1 \), by Corollary 12.11, and so has a characteristic which is a divisor of \( e_1 \). Given that the trace \( T_{L'_i/F'} (\psi_i(x_t)) \) belongs to \( D'/D'Q_1 \), we have \( \psi (T_{L/K}(x_t)) = 0 \). This implies that \( T_{L/K}(x_t) \in P' \), hence
\[
t_{T_{L/K}}(x_t) = T_{L/K}(x_t) \in P' = C't \implies T_{L/K}(x_t) \in C'.
\]
If $y \in D'$, then $xy \in J$, because $J$ is a $D'$-module. It follows that $T_{L/K}(xy) \in C'$, which shows that $x \in D'$, as required. We have shown that $s_1 \geq e_1 \implies s_1 \neq e_1 - 1$.

This finishes the proof of part b.

c. The case where the characteristic of $D/Q$ does not divide $e_Q$ We will use the notation defined in a. and b. For example, we set $P = C \cap Q$ and suppose that $DP = Q_1^{e_1} \cdots Q_m^{e_m}$, with $Q = Q_1$. Let $x \in D'$ be such that $\psi_1(x) \in D'/D'Q_1$ has nonzero trace, i.e., $T_{L'/F'}(\psi_1(x)) \neq 0$. (For example, we could take $x = 1$.) From Proposition 15.6 there exists $y \in D'$ such that $y - x \in D'Q_1$ and $y \in D'Q_i$, for $i = 2, \ldots, m$. On the one hand, $\psi_1(y) = \psi_1(x) \neq 0$, and so $\psi_1(y)$ has nonzero trace; on the other hand, for $i = 2, \ldots, m$ such that $e_i \neq 0$, $y \in D'Q_i$, hence $\psi_1(y) = 0$. Applying Theorem 15.4 we obtain

$$\psi(T_{L/K}(y)) = \sum_{i=1}^{m} e_i T_{L'/F'}(\psi_1(y)) = e_1 T_{L'/F'}(\psi_1(y)) \neq 0,$$

because the characteristic of $D'/D'Q_1$ (equal to that of $D/Q_1$) does not divide $e_1$. Therefore

$$T_{L/K}(y) = T_{D'/C'}(y) \notin P' = C' t \implies T_{L/K}(\frac{y}{t}) \notin C'.$$

Now,

$$D' = \prod_{i=1}^{m} D'Q_i^e i \implies D'Q_1^{-e_1} = (D')^{-1} \prod_{i=2}^{m} D'Q_i^e.$$

Also, $\frac{1}{t} \in (D')^{-1}$, because $(D')^{-1} = D'_{\frac{1}{t}}$, and, for $i = 2, \ldots, m$,

$$y \in D'Q_i^e \implies y \in \cap_{i=2}^{m} D'Q_i^e = \prod_{i=2}^{m} D'Q_i^e,$$

because the ideals $D'Q_i^e$ are pairwise coprime. Therefore

$$\frac{y}{t} \in (D')^{-1} \prod_{i=2}^{m} D'Q_i^e = D'Q_1^{-e_1}.$$

Given that $\frac{y}{t} \notin D'$, it must be so that $D'Q_1^{-e_1}$ is not included in $D'$.

Suppose now that $s_1 \geq e_1$. Then $D'Q_i^e \prod_{i=2}^{m} D'Q_i^e$ divides $\prod_{i=1}^{m} D'Q_i^e$, which implies that $D'Q_i^e$ divides $\prod_{i=1}^{m} D'Q_i^e$, i.e.,

$$D'Q_1^e \prod_{i=2}^{m} D'Q_i^e \implies D'Q_1^{-e_1} \subset D',$$

a contradiction. Therefore $e_1 > s_1 \geq e_1 - 1 \implies s_1 = e_1 - 1$, as required. \hspace{1cm} \Box

The theorem which we have just proved has an important consequence.

237
Corollary 15.3 A nonzero prime ideal $Q$ in $D$ is ramified in $L/K$ if and only if $Q$ divides the different $\Delta_{L/K}$. Hence $D$ has only a finite number of ramified prime ideals.

Proof If $Q$ is ramified in $L/K$, then $e_Q \geq 2$, which implies that $s_Q \geq 1$ and so $Q$ divides the different $\Delta_{L/K}$. On the other hand, if $Q$ is not ramified in $L/K$, then $e_Q = 1$, which implies that $s_Q = 0$, so $Q$ does not divide the different $\Delta_{L/K}$. \qed

15.6 Total ramification

We recall the definition of a totally ramified prime ideal or prime number. Let $K \subset L$ be number fields such that $L/K$ is Galois and $[L : K] = n < \infty$. We set $R = O_K$ and $S = O_L$ and suppose that $P$ is a nonzero prime ideal in $R$. If there is a prime ideal $Q$ in $S$ such that $SP = Q^n$, then we say that $P$ is totally ramified in $S$. If $K = \mathbb{Q}$ and $p \in \mathbb{Z}$ is a prime number, then we say that $p$ is totally ramified in $S$ if the ideal $(p)$ is totally ramified in $S$.

Example 1 + $i$ is irreducible in $\mathbb{Z}[i]$, so prime. Hence $(1 + i)$ is a prime ideal in $\mathbb{Z}[i]$. As $\mathbb{Z}[i]2 = (1 + i)^2$, the prime number 2 is totally ramified in $\mathbb{Z}[i]$.

We will presently return to the context of number fields; however, before doing so, we will establish some results in the more general context of Dedekind domains.

Proposition 15.7 Let $C$ be a Dedekind domain, $K$ its field of fractions, $L$ a finite Galois extension of $K$ and $D$ the integral closure of $C$ in $L$. We suppose that $P$ is a prime ideal in $C$ and assume that there is a unique ideal $Q$ such that $C \cap Q = P$. Finally we let $U = C \setminus P$ and set $D' = U^{-1}D$. Then $D_Q = D'$.

Proof Let $x \in D'$. As $Q \cap C = P$, if $x \notin P$, then $x \notin Q$, so $U \subset D \setminus Q$. This implies that $D' \subset D_Q$. We now must show that $D_Q \subset D'$. If every element of $D_Q$ is integral over $C'$, then $D_Q$ is contained in the integral closure of $C'$ in $L$, which is $D'$. We aim to show that this is the case. If $x \in D_Q$, then $x = \frac{a}{v}$, where $d \in D$ and $v \in D \setminus Q$. As $d$ is integral over $C$, $d$ is also integral over $C_P$, so it is sufficient to show that $\frac{1}{v}$ is integral over $C_P$. Let

$$m(v, K) = a_0 + a_1X + \cdots + a_{n-1}X^{n-1} + X^n \in C[X]$$

be the minimal polynomial of $v$ over $K$. (From Theorem 11.1, $m$ belongs to $C[X]$, because $v$ is integral over $C$.) Since $L/K$ is a Galois extension and $Q$ is the only ideal of $D$ such that $C \cap Q = P$, we have $\sigma(Q) = Q$, for all $\sigma \in \text{Gal}(L/K)$. This implies that no conjugate of $v$ lies in $Q$ and hence the product of the conjugates of $v$ is not in $Q$. Hence $a_0 \in C \setminus P$ and so $\frac{1}{v} \in C_P$. However, $\frac{1}{v}$ is a root of the polynomial

$$f(X) = \frac{1}{a_0} + \frac{a_{n-1}}{a_0}X + \cdots + \frac{a_1}{a_0}X^{n-1} + X^n \in C_P[X],$$

hence $\frac{1}{v}$ is integral over $C_P$. \qed

The next result is technical.

Proposition 15.8 Let $C$ be a Dedekind domain, $K$ its field of fractions, $L$ a finite Galois extension of $K$ and $D$ the integral closure of $C$ in $L$. We also suppose that $L = K(t)$, where $t \in D$ and we set $f = m(t, K)$ and $n = \deg f$. Then

238
• a. $T_{L/K}\left(\frac{x^i}{x(t)}\right) = 0$, for $i = 0, 1, \ldots, n-2$, and $T_{L/K}\left(\frac{x^{n-1}}{x(t)}\right) = 1$.

• b. $C[t] = \frac{1}{f'(t)}C[t]$.

**Proof a.** As $L$ is a Galois extension of $K$, we may write

$$f(X) = \prod_{k=1}^{n}(-t_k + X),$$

with $t = t_1$ and $t_1, t_2, \ldots, t_n$ distinct elements of $L$. (As $L/K$ is separable, the roots of $f$ are simple; these roots lie in $L$ because $L/K$ is normal.)

We now consider the rational fraction $\frac{1}{f}$. To begin with, the partial fraction decomposition theorem (Theorem A.9) in $L[X]$ ensures that there exist $a_1, \ldots, a_n \in L$ such that

$$\frac{1}{f(X)} = \prod_{k=1}^{n}(-t_k + X) = \sum_{k=1}^{n} a_k (-t_k + X),$$

where $a_k \in L$. Multiplying by $f(X)$ we obtain

$$1 = \sum_{k=1}^{n} \frac{f(X)a_k}{-t_k + X} = \sum_{k=1}^{n} a_k \left( \prod_{i \neq k} (-t_i + X) \right).$$

Setting $X = t_j$, we find

$$1 = \sum_{k=1}^{n} a_k \left( \prod_{i \neq k} (-t_i + t_j) \right) = a_j \prod_{i \neq j} (-t_i + t_j),$$

and so

$$a_j = \frac{1}{\prod_{i \neq j} (-t_i + t_j)} = \frac{1}{f'(t_j)}.$$

From this we obtain the expression

$$\frac{1}{f(X)} = \sum_{k=1}^{n} \frac{1}{f'(t_k)(-t_k + X)}.$$

To continue we consider the rational fraction $\frac{1}{f(X)}$ in the ring of formal Laurent series $L((\frac{1}{X}))$, composed of series of the form $\sum_{i=-\infty}^{m} a_i X^i$, with $a_i \in L$ and $m \in \mathbb{Z}$. It is easy to check that, for $k = 1, \ldots, n$,

$$(-t_k + X)^{-1} = X^{-1} + t_k X^{-2} + t_k^2 X^{-3} + \cdots,$$

hence

$$\frac{1}{f(X)} = \sum_{k=1}^{n} \frac{1}{f'(t_k)} (X^{-1} + t_k X^{-2} + t_k^2 X^{-3} + \cdots).$$

However, $\frac{1}{f(X)}$ is also equal to $\frac{1}{\prod_{k=1}^{n}(-t_k + X)}$ and so
\[
\frac{1}{f(X)} = (X^{-1} + t_1X^{-2} + t_1^2X^{-3} + \ldots) \cdots (X^{-1} + t_nX^{-2} + t_n^2X^{-3} + \ldots)
\]
\[
= X^{-n}(1 + t_1X^{-1} + t_1^2X^{-2} + \ldots) \cdots (1 + t_nX^{-1} + t_n^2X^{-2} + \ldots)
\]
\[
= X^{-n} + b_1X^{-(n+1)} + b_2X^{-(n+2)} + \ldots
\]

Comparing the two formal Laurent series for \(\frac{1}{f(X)}\) we find
\[
\sum_{k=1}^{n} \frac{t_k^n}{f'(t_k)} = 0,
\]
for \(i = 0, 1, \ldots, n - 2\), and
\[
\frac{t_k^{n-1}}{f'(t_k)} = 1.
\]

Now, using Corollary 10.3 and the fact that \(f' \in K[X]\), we obtain
\[
T_{L/K}\left(\frac{t^i}{f'(t)}\right) = \sum_{\sigma \in Gal(L/K)} \sigma\left(\frac{t^i}{f'(t)}\right)
\]
\[
= \sum_{\sigma \in Gal(L/K)} \sigma(t)^i
\]
\[
= \sum_{k=1}^{n} \frac{t_k^i}{f'(t_k)}
\]

since the sets \(\{t_1, \ldots, t_n\}\) and \(\{\sigma(t), \sigma \in Gal(L/K)\}\) are both composed of the conjugates of \(t\) (Proposition 6.2). This establishes part a. of the proposition.

b. We first show that \(\frac{1}{f'(t)} C[t] \subseteq C[t]^*\). As \(t\) is a root of a monic polynomial in \(C[X]\) of degree \(n\), there exist \(a_0, \ldots, a_{n-1} \in C\) such that
\[
t^n = a_0 + a_1t + \cdots + a_{n-1}t^{n-1}.
\]
Thus, for all \(s \geq n\), there exist \(c_0, \ldots, c_{n-1} \in C\) such that
\[
t^s = c_0 + c_1t + \cdots + c_{n-1}t^{n-1}.
\]
This implies that the set \(B = \{1, t, \ldots, t^{n-1}\}\) (resp. \(B' = \{\frac{1}{f'(t)}, \frac{t}{f'(t)}, \ldots, \frac{t^{n-1}}{f'(t)}\}\)) generates the \(C\)-module \(C[t]\) (resp. \(C\)-module \(\frac{1}{f'(t)} C[t]\)). As \(B\) and \(B'\) are clearly independant sets, they are bases of the respective \(C\)-modules \(C[t]\) and \(\frac{1}{f'(t)} C[t]\).

For \(0 \leq i \leq n - 1\) and \(0 \leq j \leq n - 1\), there exist \(d_0, \ldots, d_{n-1} \in C\) such that
\[
t^{i+j} = d_0d_1t + \cdots + d_{n-1}t^{n-1}.
\]
(For \(i + j \geq n\), this is clear; for \(i + j < n\), it is sufficient to take \(d_{i+j} = 1\) and \(d_k = 0\), for \(k \neq i + j\).) Thus
\[
T_{L/K}\left(\frac{t^i}{f'(t)}\right) = d_0T_{L/K}\left(\frac{1}{f'(t)}\right) + d_1T_{L/K}\left(\frac{t}{f'(t)}\right) + \cdots + d_{n-1}T_{L/K}\left(\frac{t^{n-1}}{f'(t)}\right) = d_{n-1}.
\]

240
from part a. Hence $T_{L/K} \left( \frac{t^{i+j}}{f(t)} \right) \in C$.

However, 
\[ C[t]^* = \{ x \in L : T_{L/K}(xz) \in C, \forall z \in C[t] \} \]

and an element of $\frac{1}{f(t)} C[t]$ (resp. $C[t]$) has the form $\sum_{i=1}^{n-1} a_i \frac{t^i}{f(t)}$ (resp. $\sum_{j=1}^{n-1} b_j t^j$). Hence, for $x \in \frac{1}{f(t)} C[t]$ and $z \in C[t]$, we have

\[ T_{L/K}(xz) = T_{L/K} \left( \sum_{i=1}^{n-1} a_i \frac{t^i}{f(t)} \sum_{j=1}^{n-1} b_j t^j \right) = \sum_{0 \leq i,j \leq n-1} a_i b_j \left( \frac{t^{i+j}}{f(t)} \right) \in C \]

and so $\frac{1}{f(t)} C[t] \subset C[t]^*$.

We now consider the reverse inclusion $C[t]^* \subset \frac{1}{f(t)} C[t]$. An element $y$ of $C[t]^*$ is in $L = K(t)$. Thus there exist $k_0, \ldots, k_{n-1} \in K$ such that

\[ y = \frac{k_0}{f(t)} + \frac{k_1 t}{f(t)} + \cdots + \frac{k_{n-1} t^{n-1}}{f(t)}. \]

(Clearly $y = \sum_{i=0}^{n-1} k_i t^i$, with $k_i \in K$; setting $k_i = k_i f^i(t)$, we obtain the required expression for $y$.) Moreover,

\[ T_{K/L}(y) = k_0 T_{L/K} \left( \frac{1}{f(t)} \right) + k_1 \left( \frac{t}{f(t)} \right) + \cdots + k_{n-1} \left( \frac{t^{n-1}}{f(t)} \right) = k_{n-1}, \]

from part a. As $y \in C[t]^*$, $T_{K/L}(y) = T_{K/L}(y1) \in C$, i.e., $k_{n-1} \in C$. Now,

\[ T_{L/K}(yt) = k_0 T_{L/K} \left( \frac{t}{f(t)} \right) + k_1 T_{L/K} \left( \frac{t^2}{f(t)} \right) + \cdots + k_{n-2} T_{L/K} \left( \frac{t^{n-1}}{f(t)} \right) + k_{n-1} T_{L/K} \left( \frac{t^n}{f(t)} \right) \]

\[ = k_{n-2} + k_{n-1} T_{L/K} \left( \frac{t^n}{f(t)} \right). \]

Since $y \in C[t]^*$ and $t \in C[t]$, we have $T_{L/K}(yt) \in C$. Also, we have shown above the existence of $c_0, \ldots, c_{n-1} \in C$ such that

\[ t^n = c_0 + c_1 t + \cdots + c_{n-1} t^{n-1} \implies T_{L/K} \left( \frac{t^n}{f(t)} \right) \in C, \]

using a. It follows that $k_{n-2} \in C$. If we replace $t$ by $t^2$, then we find that $k_{n-3} \in C$. Continuing the process we finally obtain that all the $k_i$ belong to $C$, which implies that $C[t]^* \subset \frac{1}{f(t)} C[t]$, as required.

\[ \square \]

**Corollary 15.4** Let $C$ be a Dedekind domain, $K$ its field of fractions, $L$ a finite Galois extension of $K$ and $D$ the integral closure of $C$ in $L$. We also suppose that $L = K(t)$, where $t \in D$, and we denote $f = m(t, K) \in C[X]$. Then the different $\Delta(D|C) = Df'(t)$ if and only if $D = C[t]$.

**Proof** If $D = C[t]$, then

\[ D^* = C[t]^* = \frac{1}{f(t)} C[t] = \frac{1}{f(t)} D \implies \Delta(D|C) = f'(t)D = Df'(t). \]

241
because $D^{-1} = D$. 
Now suppose that $\Delta(D|C) = Df'(t)$. As $C[t] \subset D$, we have $D^* \subset C[t]^*$, hence

$$D = D^{-1} = f'(t)D^* \subset f'(t)C[t]^* = C[t] \implies C[t] = D,$$

because $C[t] \subset D$. 

We now return to number rings, with the notation of the first paragraph of this section, i.e., $K \subset L$ are number fields such that $L/K$ is Galois and $[L : K] = n < \infty$. We set $R = \mathcal{O}_K$ and $S = \mathcal{O}_L$ and suppose that $P$ is a nonzero prime ideal in $R$ which is totally ramified in $S$: $SP = Q^n$, where $Q$ is a prime ideal in $S$. To simplify the notation, we write $\Delta_Q$ for $\Delta(S_Q|R_P)$. As $\Delta_Q$ is an ideal in $S_Q$, there exists an integer $s \geq 0$ such that $\Delta_Q = S_Q^s$. In addition, there exists $t \in S$ such that $S_Q = S_Q^t$ (Theorem 12.12 and remark before Theorem 13.16).

**Proposition 15.9** The exponent at $Q$ of $\Delta(S|R)$, i.e., the power of $Q$ in the decomposition of $\Delta(S|R)$ into prime ideals of $S$ ($s_Q(L|K)$), is equal to $s$.

**Proof** The decomposition of $\Delta(S|R)$ into prime ideals of $S$ has the form

$$\Delta(S|R) = Q_s^s L|K \prod_{i=1}^r Q_i^{\alpha_i},$$

where $Q_1, \ldots, Q_r$ are prime ideals in $S$. Setting $S' = (R \setminus P)^{-1} S$, from Proposition 12.16 the decomposition of $S'\Delta(L|K)$ into prime ideals has the form

$$S'\Delta(S|R) = (S'Q)s^s L|K \prod_{i=1}^r (S'_Q)^{\alpha_i}.$$

However, from Proposition 15.7, $S' = S_Q$, and from Theorem 15.2, $\Delta_Q = S_Q \Delta_Q$, thus

$$\Delta_Q = S_Q^s L|K \prod_{i=1}^r (S_Q Q_i)^{\alpha_i}.$$

Since the decomposition of $\Delta_Q$ is unique, we must have $s_Q(L|K) = s$ and the product of the other ideals equal to $S_Q$. 

There is an important relation between the exponent $s_Q(L|K)$ and the ramification groups $V_i$ of $Q$ in the extension $L/K$.

**Theorem 15.6** If $L/K$ is a finite Galois extension of number fields, $P$ a nonzero prime ideal of $\mathcal{O}_K$ totally ramified in $\mathcal{O}_L$, $Q$ the unique prime ideal in $\mathcal{O}_L$ lying over $P$ and

$$V_0 \supset V_1 \supset \cdots \supset V_r = \{\text{id}\}$$

are the ramification groups of $Q$ in $L/K$, then

$$s_Q(L|K) = \sum_{i=0}^{r-1} (|V_i| - 1).$$
We aim to apply Corollary 15.4, with $C = R_P$ and $D = S_Q$. However, we need to justify this.

First we show that $L = K(t)$. (As $t \in S$, we have $t \in S_Q$.) Since $K \subset L$ and $t \in S \subset L$, we must have $K(t) \subset L$. For the reverse inclusion, to begin we notice that the set $B = \{1, t, \ldots, t^{n-1}\}$ is a $K$-basis of $L$ (Corollary E.1). Thus, if $y \in L$, then there exist $a_0, a_1, \ldots, a_{n-1} \in K$ such that $y = \sum_{i=0}^{n-1} a_it^i$, hence $y \in K[t] = K(t)$. We have shown that $L = K(t)$.

Now we show that $S_Q$ is the integral closure of $R_P$ in $L$. From Corollary 12.13, $O_L$ is the integral closure of $O_K$ in $L$. Setting $U = R \setminus P$, $R' = U^{-1}R$ and $S' = U^{-1}S$, from Proposition 12.20 we obtain that $S'$ is the integral closure of $R'$ in $L$. However, by definition $R' = R_P$ and, from Proposition 15.7, $S_Q = S'$. Thus $S_Q$ is the integral closure of $R_P$ in $L$.

Our next step is to show that $S_Q = R_P[t]$. As $\sigma(Q) = Q$, for all automorphisms $\sigma \in Gal(L/K)$, the decomposition group $D = D(Q,P) = Gal(L/K)$. Thus $L^D = K$. From Corollary 13.5 and the fact that $e = n$, we obtain $f = 1$. Now, using Proposition 13.10, we see that $L^E = K$ and so $E = Gal(L/K)$. It follows that

$$S_E = O_{L^E} = O_K = R \quad \text{and} \quad Q^E = P.$$ 

From Theorem 13.16 $S_Q$ is a free module over $S_P^E = R_P$, with basis $B = \{1, t, \ldots, t^{n-1}\}$, where $t \in S$ is a generator of the principal ideal $S_Q$. Hence $S_Q = R_P[t]$ as required.

We have shown the conditions for applying Corollary 15.4, with $C = R_P$ and $D = S_Q$, are met. Thus $\Delta = S_Qf'(t)$, where $f = m(t, K)$. (This makes sense, because $f \in R[X]$ and $R \subset R_P \subset S_Q$, which implies that $f'(t) \in S_Q$.) To simplify the notation we set $G = Gal(L/K)$. Then

$$f(X) = \prod_{\sigma \in G} (-\sigma(t) + X) \implies f'(t) = \prod_{\sigma \in G, \sigma \neq id} (-\sigma(t) + t).$$

We may partition the elements of $G$ into disjoint subsets $V_m/V_{m+1}$, for $m = 0, 1, \ldots, r - 1$. If $\sigma \in V_m \setminus V_{m+1}$, then, from Proposition 13.16, $\sigma(t) - t \in Q^{m+1} \setminus Q^{m+2}$. As $S_Q(\sigma(t) - t)$ is an ideal of $S_Q$, there exists $s(\sigma) \in \mathbb{N}$ such that $S_Q(\sigma(t) + t) = S_Q^{s(\sigma)}$. With $s$ as defined in the paragraph before Proposition 15.9, we obtain

$$S_Qt^s = \Delta_Q = S_Qf'(t) = S_Q \prod_{\sigma \in G, \sigma \neq id} (-\sigma(t) + t) = \prod_{\sigma \in G} S_Q^{s(\sigma)}.$$ 

Therefore

$$s = \sum_{\sigma \in G, \sigma \neq id} s(\sigma) = \sum_{m=0}^{r-1} \sum_{\sigma \in V_m \setminus V_{m+1}} s(\sigma).$$

We need to determine the values $s(\sigma)$, for $\sigma \in V_m \setminus V_{m+1}$. If $\sigma \in V_m \setminus V_{m+1}$, then

$$S_Q^{s(\sigma)} = S_Q(-\sigma(t) + t) = S_QQ^{m+1} = S_Q^{m+1},$$

which implies that $s(\sigma) = m + 1$. As there are $|V_m| - |V_{m+1}|$ elements in $V_m \setminus V_{m+1}$, we have

$$\sum_{m=0}^{r-1} \sum_{\sigma \in V_m \setminus V_{m+1}} s(\sigma) = \sum_{m=0}^{r-1} (|V_m| - |V_{m+1}|)(m + 1).$$

Writing $A$ for the sum on the right hand side, we have

$$A = (|V_0| - |V_1|)1 + (|V_1| - |V_2|)2 + \cdots + (|V_{r-1}| - |V_r|)r = |V_0| + |V_1| + \cdots + |V_{r-1}| - r,$$

because $V_r = \{id\}$. Simplifying the right hand side, we find $\sum_{m=0}^{r-1}(|V_m| - 1)$. However, from Proposition 15.9, $s = s_Q(L/K)$, hence the result.

Chapter 16

The Kronecker-Weber theorem

In this chapter we present and prove one of the principle theorems of algebraic number theory. The proof is long and needs certain preliminary results, which we handle in detail. The theorem states that any abelian finite normal extension of the rationals is included in a cyclotomic extension. Our proof follows that given in [18].

16.1 Preliminaries

We begin with a sufficient condition for a prime number to be totally ramified in a number ring.

**Proposition 16.1** If $L/\mathbb{Q}$ is a finite normal abelian extension such that the discriminant $\text{disc}(O_L)$ is a power of a prime $p$, then $p$ is totally ramified in $O_L$.

**Proof** We need to show that there is a unique prime ideal $Q$ in $O_L$ lying over $p$ and that its inertial degree is 1. Let $Q$ be a prime ideal in $O_L$ lying over $p$. To simplify the notation we set $E = E(Q|\mathbb{Z}p)$. As usual we write $L_E$ for the fixed field of $E$. We claim that no prime number divides the discriminant $\text{disc}(O_{L_E})$. Indeed, if $q$ is such a prime number, then $q$ ramifies in $O_{L_E}$, hence in $O_L$. Thus $q$ divides $\text{disc}(O_L)$, which is a power of $p$ and so $q = p$. So we need to show that $p$ does not ramify in $O_{L_E}$.

To see this, let $Q_1$ be a prime ideal in $O_{L_E}$ lying over $p$ and $Q_2$ a prime ideal in $O_L$ lying over $Q_1$. Then $Q$ and $Q_2$ are both prime ideals in $O_L$ lying over $p$. As the Galois group $G = \text{Gal}(L/\mathbb{Q})$ is abelian, from Exercise 13.4 we deduce that $E(Q_2|\mathbb{Z}p) = E$. Now, $Q_1$ is the unique prime ideal in $O_{L_E}$ lying under $Q_2$, so, from Proposition 13.14, we have $e(Q_1|\mathbb{Z}p) = 1$, i.e., $p$ is unramified in $O_{L_E}$, as required, which implies that $p$ does not divide $\text{disc}(O_{L_E})$.

As no prime number divides $\text{disc}(O_{L_E})$, from Theorem 14.5 we must have $L_E = \mathbb{Q}$. Since $Q \subset L_D \subset L_E$, it is also the case that $L_D = \mathbb{Q}$. From Theorem 6.7, we obtain

$$\text{Gal}(L/\mathbb{Q}) = \text{Gal}(L/L_D) = D.$$ 

Let $Q$ and $Q'$ be prime ideals in $O_L$ lying over $p$. Given that $L/\mathbb{Q}$ is normal, there exists $\sigma \in \text{Gal}(L/\mathbb{Q})$ such that $\sigma(Q) = Q'$. However, $\text{Gal}(L/\mathbb{Q}) = D(Q|\mathbb{Z}p)$, which implies that $Q = Q'$ and so there is a unique prime ideal in $O_L$ lying over $p$.

We now consider the inertial degree $f(Q|p)$. Proposition 13.10 assures that $[L_E : L_D] = f(Q|p)$. As $L_E = L_D$, we have $f(Q|p) = 1$ and so $p$ is totally ramified in $O_L$. \hfill \square
Example Let \( \zeta \) be a \( p^r \)th primitive root of unity, where \( p \) is an odd prime and \( r \geq 1 \), and \( K = \mathbb{Q}(\zeta) \). From Theorem 11.15 we know that the discriminant \( \text{disc}(O_K) \) is a power of \( p \), hence \( p \) is totally ramified in \( O_K \).

If \( L \) is a number field as in Proposition 16.1, i.e., \( L/\mathbb{Q} \) is a finite normal abelian extension such that the discriminant \( \text{disc}(O_L) \) is a power of a prime \( p \), and \( K \) a number field included in \( L \), then \( K/\mathbb{Q} \) is also a finite normal abelian extension. This follows from Theorem 6.6: We can write \( K = L^H \), where \( H \) is a subgroup of \( G = \text{Gal}(L/\mathbb{Q}) \), which is normal, because the Galois group is abelian. It follows that \( K/\mathbb{Q} \) is a normal extension. Also, the Galois group \( G' = \text{Gal}(K/\mathbb{Q}) \) is isomorphic to the quotient group \( G/H \), which is abelian, because \( G \) is abelian. To simplify the notation we write \( S = O_L \) and \( R = O_K \). Let \( Q \) be the unique prime ideal of \( S \) lying over \( p \) and \( Q_1 \) the unique prime ideal of \( R \) lying under \( Q \). We aim to show that, if \([K : \mathbb{Q}] = p\), then \( s_{Q_1}(K|\mathbb{Q}) \), the exponent at \( Q_1 \) of the different \( \Delta(K|\mathbb{Q}) \), is independant of the field \( K \) which we choose.

Proposition 16.2 Let \( L/\mathbb{Q} \) be a finite normal abelian extension such that the discriminant \( \text{disc}(O_L) \) is a power of an odd prime \( p \) and \( K \) a number field included in \( L \) whose degree over \( \mathbb{Q} \) is \( p \). Then \( p \) is totally ramified in \( R \) and, if \( Q_1 \) denotes the unique prime ideal of \( R \) lying over \( p \), then \( s_{Q_1}(K|\mathbb{Q}) = 2(p - 1) \), where \( s_{Q_1}(K|\mathbb{Q}) \) is the exponent at \( Q_1 \) of the different \( \Delta(K|\mathbb{Q}) \).

Proof Our first step is to show that \( p \) is totally ramified in \( R \). Suppose that \( Q_2 \) and \( Q_3 \) are distinct prime ideals in \( R \) lying over \( p \). Then \( Q_2 \) (resp. \( Q_3 \)) lies under a prime ideal \( Q_2' \) (resp. \( Q_3' \)) in \( S \). Clearly \( Q_2' \) and \( Q_3' \) are distinct and lie over \( p \). As \( p \) is totally ramified in \( S \), this is impossible, hence there is a unique prime ideal in \( R \) lying over \( p \). We also notice that

\[
1 = f(Q'|p) = f(Q|Q_1)f(Q_1|p) \Rightarrow f(Q_1|p) = 1
\]

and so \( p \) is totally ramified in \( R \), or equivalently, \( \mathbb{Z}p \) is totally ramified in \( R \).

We now apply Theorem 15.6 to obtain

\[
s_{Q_1}(K|\mathbb{Q}) = \sum_{i=0}^{r-1}(|V'_i| - 1),
\]

where \( V'_i \) denotes the \( i \)th ramification group of \( Q_1 \) in the extension \( K/\mathbb{Q} \). Now, each \( V'_i \) is a subgroup of \( \text{Gal}(K/\mathbb{Q}) \) and \( |\text{Gal}(K/\mathbb{Q})| = [K : \mathbb{Q}] = p \), so \( |V'_i| \) has the value \( 1 \) or \( p \) and it follows that \( p - 1 \) divides \( s_{Q_1}(K|\mathbb{Q}) \).

In the spirit of the discussion before Proposition 15.9, we write \( \Delta Q_1 = \Delta(R_{Q_1}|\mathbb{Z}p) \), which is an ideal in \( R_{Q_1} \). In addition, there exists \( t \in R \) such that \( R_{Q_1}Q_1 = R_{Q_1}t \) and an integer \( s > 0 \) such that \( \Delta Q_1 = R_{Q_1}Q_1^s = R_{Q_1}t^s \). Proposition 15.9 tells us that \( s_{Q_1}(K|\mathbb{Q}) = s \). We will use this relation to determine the precise value of \( s_{Q_1}(K|\mathbb{Q}) \).

We aim to use Corollary 15.4 with \( C = \mathbb{Z}_{p^r} \) and \( D = R_{Q_1} \) and respective fields of fractions \( \mathbb{Q} \) and \( K \). We need to check that the conditions of the corollary are satisfied. \( R = O_K \) is the integral closure of \( \mathbb{Z} \) in \( K \) by definition; Proposition 15.7 then assures us that \( R_{Q_1} \) is the integral closure of \( \mathbb{Z}_{p^r} \) in \( K \). Showing that \( K = \mathbb{Q}(t) \), with \( t \in R_{Q_1} \), is a little more difficult.

We claim that \( R_{Q_1} \) is a free module over \( \mathbb{Z}_{p^r} \), with basis \( B = \{1, t, \ldots, t^{p-1}\} \). To establish this we use Theorem 13.16. We set \( E = E(Q_1|\mathbb{Z}p) \) and \( D = D(Q_1|\mathbb{Z}p) \). From Proposition 13.10,

\[
[K^E : K^D] = f(Q_1|p) = 1 \implies K^E = K^D.
\]

245
For all \( \sigma \in G = \text{Gal}(K/\mathbb{Q}) \), we have \( \sigma(Q_1) = Q_1 \), because \( Q_1 \) is the only prime ideal lying over \( p \). This implies that \( G \subset D \) and so \( D = G \) Thus
\[
K^E = K^D = K^G = \mathbb{Q}.
\]
and so
\[
R^E = O_{K^G} = O_{\mathbb{Q}} = \mathbb{Z}.
\]
Continuing we have
\[
Q_1^E = R^E \cap Q_1 = \mathbb{Z} \cap Q_1 = \mathbb{Z}_p \Rightarrow R_{Q_1}^E = \mathbb{Z}_p.
\]
In addition, \( e = e(Q_1|p) = p \). From Theorem 13.16 we obtain that \( R_{Q_1} \) is a free module over \( \mathbb{Z}_p \), with basis \( B = \{1, t, \ldots, t^{p-1}\} \), as required.
From Corollary E.1, \( B \) is a basis of \( K \) over \( \mathbb{Q} \), which implies that \( K = \mathbb{Q}[t] = \mathbb{Q}(t) \).

Now we have the conditions for applying Corollary 15.4. Also, we have seen that \( R_{Q_1} \) is a free module over \( \mathbb{Z}_p \) and so \( R_{Q_1} \cong \mathbb{Z}_p[t] \). It follows that
\[
\Delta(R_{Q_1})\mathbb{Z}_p = R_{Q_1}f'(t),
\]
where \( f \) is the minimal polynomial \( m(t, \mathbb{Q}) \). If
\[
f(t) = a_0 + a_1t + \cdots + a_{p-1}t^{p-1} + t^p,
\]
then \( f \in \mathbb{Z}[X] \) and
\[
f'(t) = a_1 + 2a_2t + \cdots + (p-1)a_{p-1}t^{p-2} + pt^{p-1}.
\]
We notice that
\[
Rp = R\mathbb{Z}_p = Q_1^p,
\]
because \( \mathbb{Z}_p \) is totally ramified in \( R \) and \( Q_1 \) is the unique prime ideal of \( R \) lying over \( \mathbb{Z}_p \). Hence,
\[
R_{Q_1}p = R_{Q_1}Rp = R_{Q_1}Q_1^p = R_{Q_1}t^p,
\]
thus
\[
R_{Q_1}pt^{p-1} = (R_{Q_1}p)(R_{Q_1}t^{p-1}) = R_{Q_1}t^{2p-1},
\]
from which we deduce that there exists \( \alpha_p \in R_{Q_1} \) such that \( pt^{p-1} = \alpha_pt^{2p-1} \). It is important to notice that \( t^f|\alpha_p \). If \( t|\alpha_p \), then \( pt^{p-1} = \alpha_pt^{2p} \), with \( \alpha'_p \in R_{Q_1} \) and we obtain
\[
R_{Q_1}t^{2p-1} \subset R_{Q_1}t^{2p} \Rightarrow R_{Q_1}t^{2p-1} = R_{Q_1}t^{2p},
\]
Thus
\[
(R_{Q_1})^{2p-1} = (R_{Q_1})^{2p},
\]
which is impossible, because \( R_{Q_1}Q_1 \) is a nonzero prime ideal in the Dedekind domain \( R_{Q_1} \).

For \( i = 0, 1, \ldots, p-1 \) such that \( v_p(ia_i) \geq 0 \), we can write \( ia_i = p^{v_p(ia_i)}b_i \), where \( p \nmid b_i \). Then
\[
R_{Q_1}ia_it^{i-1} = (R_{Q_1}ia_i)(R_{Q_1}t^{i-1}) = (R_{Q_1}p^{v_p(ia_i)})(R_{Q_1}b_i)(R_{Q_1}t^{i-1}).
\]
As \( p \nmid b_i \), \( b_i \) is invertible in \( R_{Q_1} \), we have \( R_{Q_1}b_i = R_{Q_1} \) and thus
\[
R_{Q_1}ia_it^{i-1} = R_{Q_1}p^{v_p(ia_i)}R_{Q_1}t^{i-1} = R_{Q_1}t^{v_p(ia_i)+i-1},
\]
246
from which we deduce that there exists \( \alpha_i \in R_Q \) such that \( ia_i t^{i-1} = \alpha_i t^{pv_p(i a_i) + i - 1} \). We notice that \( t \mid \alpha_i \). If \( t \mid \alpha_i \), then \( ia_i t^{i-1} = \alpha'_i t^{pv_p(i a_i) + i} \), with \( \alpha'_i \in R_Q \) and so

\[
R_Q, t^{pv_p(i a_i) + i - 1} \subset R_Q, t^{pv_p(i a_i) + i} \Rightarrow R_Q, t^{pv_p(i a_i) + i - 1} = R_Q, t^{pv_p(i a_i) + i},
\]

or

\[
(R_Q, t^{pv_p(i a_i) + i - 1}) = (R_Q, t^{pv_p(i a_i) + i}),
\]

which is impossible, because \( R_Q, Q_1 \) is a nonzero prime ideal in the Dedekind domain \( R_Q \).

We notice that the integers \( pv_p(i a_i) + i - 1 \), for \( i = 0, 1, \ldots, p - 1 \), with \( ia_i \neq 0 \), and \( 2p - 1 \) are distinct. If \( m \) is the minimum of these integers and \( \alpha_{m_0} \) corresponds to the minimum, then

\[
f'(t) = (\alpha_{m_0} + \beta t) t^m,
\]

where \( \alpha_{m_0}, \beta \in R_Q \) and \( t \mid \alpha_{m_0} \). Thus,

\[
t \mid (\alpha_{m_0} + t \beta) \Rightarrow \alpha_{m_0} + \beta t \notin R_Q, t = R_Q, Q_1,
\]

the unique maximal ideal of \( R_Q \). From Exercise 12.11, the element \( \alpha_{m_0} + \beta t \) is invertible in \( R_Q \), and hence

\[
R_Q, f'(t) = R_Q, t^m \Rightarrow s_Q, (K|Q) = m.
\]

We now conclude. By definition of the minimum \( m \), we have \( s_Q, (K|Q) \leq 2p - 1 \). Also, from Theorem 15.5, \( s_Q, (K|Q) \geq p - 1 \). The characteristic of the field \( R/Q_1 \) is \( p \), because \( p \in Q_1 \), hence \( s_Q, (K|Q) \neq p - 1 \), which implies that \( s_Q, (K|Q) \geq p \). Putting this information together, we obtain

\[
1 < \frac{p}{p - 1} \leq \frac{s_Q, (K|Q)}{p - 1} \leq \frac{2p - 1}{p - 1} = 2 + \frac{1}{p - 1} < 3,
\]

because \( p \neq 2 \). Therefore \( \frac{s_Q, (K|Q)}{p - 1} = 2 \), as required. \( \square \)

Having developed some preliminary results, we will now turn to the proof of the theorem. We will proceed by steps.

16.2 Step 1: \([L : Q] \) and \( \text{disc}(O_L) \) are both powers of the same odd prime.

Let \( L/Q \) be a finite normal abelian extension such that the discriminant \( \text{disc}(O_L) \) is a power of a prime \( p \). Then Proposition 16.1 ensures that \( p \) is totally ramified in \( O_L \). We have also seen that

\[
E(Q|p) = D(Q|p) = Gal(L/Q),
\]

where \( Q \) is the unique prime ideal of \( O_L \) lying over \( p \). We now suppose that \( [L : Q] \) is a power of the same prime number \( p \). Then Proposition 13.18 b. ensures that \( E(Q|Z|p) = V_1(Q|Z|p) \). Indeed, as \( p \) is totally ramified \( e(Q|p) = [L : Q] \), which is a power of \( p \); this in turn implies that \( |E/V_1| = 1 \) and it follows that \( E(Q|Z|p) = V_1(Q|Z|p) \). We now aim to show that there is a unique field extension \( K \) of \( Q \) of degree \( p \) contained in \( L \). To do this we will use Proposition 16.2.
Proposition 16.3 Let $L/Q$ be a finite normal abelian extension such that $\text{disc}(O_L)$ and $[L : Q]$ are both powers of the same odd prime $p$. We suppose that $Q$ is the unique prime ideal of $O_L$ lying over $\mathcal{Z}_p$ and that $V_j(Q|\mathcal{Z}_p)$, for $j \geq 0$, are the higher ramification groups. In addition, we let $i$ be the smallest index $j$ such that $V_j(Q|\mathcal{Z}_p) \neq \text{Gal}(L/Q)$. Then $i \geq 2$, $[L^{V_i}(Q|\mathcal{Z}_p) : Q] = p$ and $L^{V_i}(Q|\mathcal{Z}_p)$ is the only field extension of degree $p$ over $Q$ contained in $L$.

PROOF From hereon, to simplify the notation, we will write $E$ for $E(Q|\mathcal{Z}_p)$ and $V_j$ for $V_j(Q|\mathcal{Z}_p)$.

By definition $V_0 = E$, and in the preamble to the proposition we have seen that $E = \text{Gal}(L/Q)$, which implies that $i \geq 1$. However, we have also seen that $V_1 = \text{Gal}(L/Q)$, hence $i \geq 2$. Now we establish that $[L^{V_1} : Q] = p$. Since $V_{i-1} = \text{Gal}(L/Q)$, we have

$$[L^{V_1} : Q] = [\text{Gal}(L/Q)/V_1] = |V_{i-1}/V_i|.$$  

From Theorem 13.18, $V_{i-1}/V_i$ is isomorphic to a subgroup of the additive group of $S/Q$, because $i \geq 2$. As $p$ is totally ramified in $O_L$, we have

$$1 = f(Q|\mathcal{Z}_p) = [S/Q : \mathcal{Z}/\mathcal{Z}_p],$$

which implies that $S/Q$ is isomorphic to $F_p$. It follows that $|V_{i-1}/V_i| = p$, because $V_{i-1} \neq V_i$.

Now let $K$ be a number field contained in $L$ whose degree over $Q$ is $p$. We aim to show that $K = L^{V_i}$. We set $R^i = O_K$ and $Q_1 = R^i \cap Q$. Then $Q_1$ is totally ramified in $S = O_L$. There is a unique ideal in $S$ lying over $Q_1$, namely $Q$, and

$$1 = f(Q|\mathcal{Z}_p) = f(Q|Q_1)f(Q_1|\mathcal{Z}_p) \Rightarrow f(Q|Q_1) = 1.$$  

By definition (Section 15.3), we have

$$\Delta_{Q_1}(L|K) = \Delta((R^1 \setminus Q_1)^{-1}S|R_Q^1).$$

Using Proposition 15.8 we obtain

$$\Delta_{Q_1}(L|K) = \Delta(S_Q|R_{Q_1}^1).$$

To simplify the notation we will write $\Delta_Q(L|K)$ for $\Delta_{Q_1}(L|K)$.

Next we set $R^2 = O_{L^{V_1}}$ and $Q_2 = R^2 \cap Q$. Then $Q_2$ is totally ramified in $S = O_L$: There is a unique ideal in $S$ lying over $Q_2$, namely $Q$, and

$$1 = f(Q|\mathcal{Z}_p) = f(Q|Q_2)f(Q_2|\mathcal{Z}_p) \Rightarrow f(Q|Q_2) = 1.$$  

By definition (Section 15.3), we have

$$\Delta_{Q_2}(L|L^{V_1}) = \Delta((R^2 \setminus Q_2)^{-1}S|R_Q^2).$$

and, using Proposition 15.8 again, we obtain

$$\Delta_{Q_1}(L|L^{V_1}) = \Delta(S_Q|R_{Q_2}^2).$$

We simplify the notation by writing $\Delta_Q(L|L^{V_i})$ for $\Delta_{Q_2}(L|L^{V_i})$.

From Theorem 15.1 we have

$$\Delta_Q(L|Q) = \Delta_Q(L|K)S_Q\Delta_{Q_1}(K|Q) \quad (16.1)$$
and
\[ \Delta_Q(L|Q) = \Delta_Q(L|L^{V_i}) S_Q \Delta_Q(L^{V_i}|Q). \] (16.2)
To clarify these equalities, we recall the definitions of the ideals appearing in the equalities:
\[ \Delta_Q(L|Q) = \Delta(S_Q|\mathbb{Z}_{p^i}), \]
\[ \Delta_Q(L|K) = \Delta(S_Q|R_{Q_1}^1), \quad \Delta_Q(L|L^{V_i}) = \Delta(S_Q|R_{Q_2}^2) \]
and
\[ \Delta_Q_1(K|Q) = \Delta(R_{Q_1}^1|\mathbb{Z}_{p^i}), \quad \Delta_Q_2(L^{V_i}|Q) = \Delta(R_{Q_2}^2|\mathbb{Z}_{p^i}). \]

We now consider \( \Delta_Q_1(K|Q) \) and \( \Delta_Q_2(L^{V_i}|Q) \) more closely. From Proposition 16.2 we have
\[ \Delta_Q_1(K|Q) = R_{Q_1}^1 Q_1^{2(p-1)} \]
and
\[ \Delta_Q_2(L^{V_i}|Q) = R_{Q_2}^2 Q_1^{2(p-1)}. \]
As \( R_{Q_1} \) is embedded in \( S_Q \), we have
\[ S_Q \Delta_Q_1(K|Q) = S_Q Q_1^{2(p-1)}. \]
Now \( Q_1 \) is totally ramified in \( S \), so \( S Q_1 = Q^{[L:\mathbf{Z}_{p^i}]} \) and we have
\[ S_Q S Q_1 = S Q Q^{[L:K]} \iff S_Q Q_1 = S Q Q^{[L:K]} \iff S Q \Delta_Q_1(K|Q) = S Q Q^{[L:K]2(p-1)}. \]
In the same way
\[ S_Q \Delta_Q_2(L^{V_i}|Q) = S_Q Q^{[L:L^{V_i}]2(p-1)}. \]
As \( [L:K] = [L:L^{V_i}] \), we have
\[ S_Q \Delta_Q_1(K|Q) = S_Q \Delta_Q_2(L^{V_i}|Q) \]
and from equations (16.1) and (16.2) we derive
\[ \Delta_Q(L|K) = \Delta_Q(L|L^{V_i}). \]

We now show that this equality ensures that \( K = L^{V_i} \). First we notice that
\[ \Delta_Q(L|K) = (S_Q Q)^{s_Q(L|K)} \quad \text{and} \quad \Delta_Q(L|L^{V_i}) = (S_Q Q)^{s_Q(L|L^{V_i})}, \]
which implies that
\[ s_Q(L|K) = s_Q(L|L^{V_i}). \]
From Theorem 15.6
\[ s_Q(L|K) = \sum_{j=0}^{r_1-1} (|V_j(Q|Q_1)| - 1), \]
where \( V_j(Q|Q_1) \), for \( j = 0, 1, \ldots, r_1 - 1 \), are the ramification groups of \( Q \) in the extension \( L/K \). (Indeed, \( L/K \) is a Galois extension and \( Q_1 \) is totally ramified in \( S \).) The same theorem ensures that
\[ s_Q(L|L^{V_i}) = \sum_{j=0}^{r_2-1} (|V_j(Q|Q_2)| - 1), \]
where \( V_j(Q|Q_2) \), for \( j = 0, 1, \ldots, r_2 - 1 \), are the ramification groups of \( Q \) in the extension \( L/L^V \).
(Indeed, \( L/L^V \) is a Galois extension and \( Q_2 \) is totally ramified in \( S \).) We can take \( r = \max(r_1, r_2) \) in both cases.

Now we consider orders of the ramification groups. We notice that

\[
V_j(Q|Q_1) = V_j \cap H,
\]

where \( H = Gal(L/K) \) and

\[
V_j(Q|Q_2) = V_j \cap V_i,
\]

since \( V_i = Gal(L/L^V) \). Therefore, for \( j = 0, 1, \ldots, i - 1 \), we have

\[
V_j(Q|Q_1) = H \quad \text{and} \quad V_j(Q|Q_2) = V_i.
\]

Then

\[
|H| = |Gal(L/K)| = [L : K] = \left[ \frac{L : Q}{K : Q} \right] = \frac{|L : Q|}{p}
\]

and

\[
p = [L^V : Q] = |Gal(L/Q)/V_i| \implies |V_i| = \frac{|L : Q|}{p},
\]

therefore \( |H| = |V_i| \), i.e., \( |V_j(Q|Q_1)| = |V_j(Q|Q_2)| \). If \( j \geq i \), then \( V_j(Q|Q_2) = V_j \), because \( V_j \subset V_i \) and it follows that \( |V_j(Q|Q_1)| \leq |V_j(Q|Q_2)| \). As

\[
\sum_{j=0}^{r-1} \left( |V_j(Q|Q_1)| - 1 \right) = \sum_{j=0}^{r-1} \left( |V_j(Q|Q_2)| - 1 \right),
\]

we must have

\[
|V_i(Q|Q_1)| = |V_i(Q|Q_2) \implies V_i \cap H = V_i \implies V_i \subset H.
\]

However, this implies that \( K = L^H \subset L^V \). As \( K \) and \( L^V \) are subspaces of \( L \) of the same dimension, they must be equal, as required.

Our next step is to show that under the conditions we have assumed at the beginning of the section, i.e., \( p \) is an odd prime, \( L \) an abelian finite normal extension of \( Q \) of degree \( p^m \) and \( disc(O_L) = p^k \), where \( m, k \in \mathbb{N}^* \), then \( L \) is a cyclic extension of \( Q \). We will use an elementary result from group theory, namely, an abelian group of order \( p^m \), where \( p \) is a prime, with a unique subgroup of order \( p^{m-1} \), is cyclic. We need a preliminary result.

**Lemma 16.1** Let \( G \) be an abelian group of order \( p^m \), where \( p \) is a prime and \( m \geq 1 \). If \( G \) has a subgroup \( H \) of order \( p^k \) and \( k < l \leq m \), then there is a subgroup \( K \) of \( G \) containing \( H \) and having order \( p^l \).

**Proof** Suppose first that \( l = k + 1 \leq m \) and let \( \hat{G} = G/H \). Then \( |\hat{G}| = p^{m-k} \) and so, by Cauchy’s theorem, there exists an element \( \hat{x} \in G/H \) of order \( p \). Let \( K \) be the subgroup of \( G \) generated by \( H \) and \( x \). Since \( x \notin H \), the group \( H \) is properly contained in \( K \). Also,

\[
K = H \cup Hx \cup \cdots \cup Hx^{p-1} \implies |K| = p^{k+1}.
\]

Repeating the argument if necessary, we finally obtain the desired subgroup.

where \( p \) is an odd prime and \( m, k \in \mathbb{N}^* \)

We may now prove the result concerning the cyclicity of \( G \).
Proposition 16.4 If $G$ is an abelian group of order $p^m$, where $p$ is a prime, with a unique subgroup $H$ of order $p^{m-1}$, then $G$ is cyclic.

Proof Let $x \in G \setminus H$. If $x$ has order less than $p^m$, then, from Lemma 16.1, the cyclic group $(x)$ is contained in a subgroup $K$ of $G$ of order $p^{m-1}$. By hypothesis, $K$ must be equal to $H$, so $x \in H$, a contradiction. Hence $x$ has order $p^m$ and so $G$ is cyclic. \qed

We may now show that, under the conditions given above, the extension $L/Q$ is cyclic.

Theorem 16.1 Let $p$ be an odd prime, $L$ a finite normal abelian extension of $Q$ of degree $p^m$, where $m \in \mathbb{N}^*$, and $\text{disc}(O_L)$ a power of $p$. Then the extension $L/Q$ is cyclic.

Proof By hypothesis the Galois group $G = \text{Gal}(L/Q)$ is abelian of order $p^m$. From Proposition 16.3 we know that $G$ has a unique subgroup of order $p^{m-1}$. Applying Proposition 16.4 we find that $G$ is cyclic. \qed

We are now in a position to prove the Kronecker-Weber theorem in a particular case. Further on we will extend the theorem to the general case.

Theorem 16.2 If $L$ is a finite normal abelian extension of $Q$ of degree $p^m$, where $p$ is an odd prime and $m \in \mathbb{N}^*$, and $\text{disc}(O_L)$ is a power of $p$, then there exists a root of unity $\xi$ such that $L = Q(\xi)$. 

Proof Let $K = \mathbb{Q}(\xi)$, where $\xi$ is a primitive $p^{m+1}th$ root of unity. The extension $K/Q$ is a Galois extension and, writing $G = \text{Gal}(K/Q)$, from Theorem 7.7 we have 

$$|G| = [K : Q] = \deg \Phi_{p^{m+1}} = \phi(p^{m+1}) = p^m(p-1).$$

Also, by Theorem 7.7, $G$ is isomorphic to $\mathbb{Z}_p^{\times}$, which is cyclic, because the group of units of $\mathbb{Z}_p$ is cyclic, when $n$ is a power of an odd prime (see, for example, [4]).

The cyclic group $G$ has a subgroup $H$ of order $p - 1$. (If $\sigma$ is a generator of $G$, then $\sigma^p$ has order $p - 1$.) We set $K' = K^H$, then $[K' : Q] = p^m$. Since $H$ is a subgroup of $G$, $H$ is cyclic, and so, by definition, $K'$ is a cyclic extension of $Q$. We claim that the discriminant $\text{disc}(O_{K'})$ is a power of $p$. To see this, notice that a prime $q$ dividing $\text{disc}(O_{K'})$ is ramified in $O_{K'}$, hence also ramified in $O_K$, thus $q$ divides $\text{disc}(O_K)$, which is a power of $p$. It follows that $q = p$. This proves the claim.

Now we consider the composition field $LK'$. As $L$ is a finite Galois extension of $Q$, so is $LK'$ (Theorem 6.8). Both $L$ and $K'$ are normal extensions of $Q$, therefore, from Theorem 6.10, the Galois group $\text{Gal}(LK'/Q)$ is isomorphic to a subgroup of the product $\text{Gal}(L/Q) \times \text{Gal}(K'/Q)$, which is abelian. Hence $\text{Gal}(LK'/Q)$ is abelian.

Now, from the proof of Corollary 6.1, we know that the Galois groups $\text{Gal}(LK'/K')$ and $\text{Gal}(L/L \cap K')$ are isomorphic, hence

$$[LK' : Q] = [LK' : K'][K' : Q] = [L : L \cap K'][K' : Q],$$

which is a power of $p$, because $[L : L \cap K']$ divides $[L : Q]$ and $[L : Q] = p^m$. We claim that the discriminant $\text{disc}(O_{LK'})$ is also a power of $p$. If $q$ is a prime and $q|\text{disc}(O_{LK'})$, then $q$ is ramified in $O_{LK'}$. From Theorem 13.12, $q$ is ramified in $L$ or in $K'$. This means that $q|\text{disc}(O_L)$ or $q|\text{disc}(O_{K'})$. In both cases we obtain $q = p$, so $\text{disc}(O_{LK'})$ is a power of $p$, as claimed.

We now apply Theorem 16.1 to $LK'$: the Galois group $\text{Gal}(LK'/Q)$ is cyclic. Both $L$ and $K'$ are normal extensions of $L \cap K'$. With $L \cap K' = F$ in Theorem 6.10, we obtain $\text{Gal}(LK'/L \cap K') \simeq \text{Gal}(L/L \cap K') \times \text{Gal}(K'/L \cap K')$. 

251
We notice that both $\text{Gal}(L/L \cap K')$ and $\text{Gal}(K'/L \cap K')$ have orders a power of $p$ and are cyclic, because $\text{Gal}(L/L \cap K')$ is a subgroup of $\text{Gal}(L/Q)$ and $\text{Gal}(K'/L \cap K')$ a subgroup of $\text{Gal}(K'/Q)$.

We have seen that $\text{Gal}(LK'/Q)$ is abelian, thus $\text{Gal}(LK'/L \cap K')$ is also abelian. The previous isomorphism gives us a primary decomposition of this finite abelian group. Moreover, $\text{Gal}(LK'/L \cap K')$ is a cyclic $p$-group, since $\text{Gal}(LK'/Q)$ is a cyclic $p$-group. Thus $\text{Gal}(LK'/L \cap K')$ is its own primary decomposition. The uniqueness of the primary decomposition ensures that $\text{Gal}(L/L \cap K')$ or $\text{Gal}(K'/L \cap K')$ is trivial. In the first case,

$$L = L \cap K' \implies L \subset K'.$$

In the second case

$$K' = L \cap K' \implies K' \subset L$$

hence

$$[L : Q] = [L : K'][K' : Q] \implies [L : K'] = 1,$$

because $[L : Q] = p^m = [K' : Q]$. Therefore $L = K'$. In both cases we have found a cyclotomic extension containing $L$. This finishes the proof.

\section*{16.3 Step 2: $[L : Q]$ and $\text{disc}(O_L)$ are both powers of 2.}

Up to here we have considered the case where the order of the Galois group $\text{Gal}(L/Q)$ is the power of an odd prime $p$ and the discriminant $\text{disc}(O_L)$ a power of the same prime. It should be clear that certain arguments we have used will not work if the prime $p$ is 2. In this section we aim to look at this case. We will first consider real fields, i.e., subfields of the field of real numbers $\mathbb{R}$. To begin we establish a preliminary result analogous to Theorem 16.1.

\begin{proposition}
Let $L$ be a real field which is a finite normal abelian extension of $Q$ of degree a power of 2 such that the discriminant $\text{disc}(O_L)$ is also a power of 2. Then the extension $L/Q$ is cyclic.
\end{proposition}

\begin{proof}
Let $[L : Q] = 2^m$, with $m \in \mathbb{N}^*$. We first consider the case where $m = 1$, i.e., $[L : Q] = 2$. Then $L = Q(\sqrt{d})$, where $d$ is a square-free integer. In this case $\text{disc}(O_L) = d$, if $d \equiv 1 \pmod{4}$, and $\text{disc}(O_L) = 4d$, if $d \equiv 2, 3 \pmod{4}$. As $\text{disc}(O_L)$ is a power of 2, the only possibility is $d = 2$ and so $L = Q(\sqrt{2})$ (and $\text{disc}(O_L) = 8$). Thus the extension $L/Q$ is cyclic.

Now suppose that $m \geq 2$. From Lemma 16.1 we know that the Galois group $\text{Gal}(L/Q)$ contains a subgroup $H$ whose order is $2^{m-1}$. For any such subgroup $H$, from Theorem 6.6,

$$[L^H : Q] = \left| \frac{\text{Gal}(L/Q)}{H} \right| = 2.$$

Moreover, $\text{disc}(O_L)$ is a power of 2, since any prime $q$ dividing $\text{disc}(O_{L,H})$ ramifies in $O_{L,H}$ and so ramifies in $O_L$. As 2 is the only prime ramifying in $O_L$, $q = 2$. Thus $\text{disc}(O_{L,H})$ is a power of 2 up to sign. As $[L^H : Q] = 2$, $L^H = Q(\sqrt{d})$, where $d$ is a square-free integer, and $\text{disc}(O_{L,H}) = d$ or $\text{disc}(O_{L,H}) = 4d$. It follows that $d = \pm 2$. Since $L^H \subset L$, $d = 2$ and so $L^H = Q(\sqrt{2})$ and $H = \text{Gal}(L/Q(\sqrt{2}))$. We conclude that the Galois group $\text{Gal}(L/Q)$ has a unique subgroup of order $2^{m-1}$. Applying Proposition 16.4 we obtain that $\text{Gal}(L/Q)$ is cyclic.

\end{proof}

We now establish another result concerning real extensions.
Proposition 16.6 If \( m \in \mathbb{N}^* \) and \( \zeta \) a primitive root of order \( 2^{m+2} \), then \( L = \mathbb{Q}(\zeta) \cap \mathbb{R} \) is the unique real finite normal abelian extension \( K \) of \( \mathbb{Q} \) such that \( [K : \mathbb{Q}] = 2^m \) and \( \text{disc}(O_K) \) is a power of 2. In addition, \( L \subset \mathbb{Q}(\zeta) \).

Proof We will begin by showing that \( L \) satisfies the conditions. \( L \) is clearly a real field and \( L \subset \mathbb{Q}(\zeta) \). Any prime \( q \) dividing the discriminant \( \text{disc}(O_L) \) ramifies in \( O_L \), hence in \( \mathbb{Q}(\zeta) \). This implies that \( q \) divides \( \text{disc}(O_{\mathbb{Q}(\zeta)}) \), which is a power of 2, by Theorem 11.15. Thus \( q = 2 \) and it follows that \( \text{disc}(O_L) \) is a power of 2.

Now
\[
[\mathbb{Q}(\zeta) : \mathbb{Q}] = \deg \Phi_{2^{m+2}} = \phi(2^{m+2}) = 2^{m+1},
\]
where \( \phi \) is Euler’s totient function. From the primitive element theorem (Theorem 3.4), there exists \( \alpha \in \mathbb{Q}(\zeta) \) such that \( \mathbb{Q}(\zeta) = L(\alpha) \). If \( \alpha = a + bi \), then \( \alpha \) is a root of the polynomial \( f(x) = (a^2 + b^2) - 2ax + x^2 \). Moreover, \( \bar{\alpha} = a - bi \in \mathbb{Q}(\zeta) \), because \( \bar{\alpha} \) is a root of the minimal polynomial \( m(\alpha, \mathbb{Q}) \) and \( \mathbb{Q}(\zeta) \) is a normal extension of \( \mathbb{Q} \). Hence
\[
a = \frac{\alpha + \bar{\alpha}}{2} \in L \quad \text{and} \quad b = \frac{\alpha - \bar{\alpha}}{2i} \in L,
\]
since \( i = \zeta^4 = \zeta^{2^m} \in \mathbb{Q}(\zeta) \). It follows that \( f \in L[X] \) and \( \deg m(\alpha, L) = 1 \) or 2. As \( \alpha \notin L \), we have \( \deg m(\alpha, L) = 2 \) and so \( [\mathbb{Q}(\zeta) : L] = 2 \). As
\[
[\mathbb{Q}(\zeta) : \mathbb{Q}] = [\mathbb{Q}(\zeta) : L][L : \mathbb{Q}],
\]
we have \( [L : \mathbb{Q}] = 2^m \), as required.

It remains to show that \( L \) is unique. Let \( F \) and \( K \) be two fields satisfying the conditions in the statement of the proposition. We aim to show that \( F = K \). Both \( F \) and \( K \) satisfy the assumptions of Proposition 16.5, so the compositum \( FK \) also satisfies the assumptions. Indeed, the extensions \( F/\mathbb{Q} \) and \( K/\mathbb{Q} \) are both normal, so \( FK/\mathbb{Q} \) is normal and the Galois group \( \text{Gal}(FK/\mathbb{Q}) \) is isomorphic to a subgroup of the product \( \text{Gal}(F/\mathbb{Q}) \times \text{Gal}(K/\mathbb{Q}) \), by Theorem 6.10. Therefore \( \text{Gal}(FK/\mathbb{Q}) \) is abelian of order a power of 2. If a prime \( q \) divides the discriminant \( \text{disc}(O_{FK}) \), then it is ramified in \( O_{FK} \) and hence ramified in \( O_F \) or in \( O_K \) (Theorem 13.12). Thus \( q \) divides \( \text{disc}(O_F) \) or \( \text{disc}(O_K) \), which are both powers of 2. Hence \( q = 2 \) and it follows that \( \text{disc}(O_{FK}) \) is a power of 2.

Now, from Theorem 6.10,
\[
\text{Gal}(FK/F \cap K) \cong \text{Gal}(F/F \cap K) \times \text{Gal}(K/F \cap K).
\]
As \( \text{Gal}(FK/F \cap K) \) is a subgroup of the abelian group \( \text{Gal}(FK/\mathbb{Q}) \), \( \text{Gal}(FK/F \cap K) \) is abelian. Both \( \text{Gal}(F/F \cap K) \) and \( \text{Gal}(K/F \cap K) \) are cyclic and of order a power of 2, being respectively subgroups of \( \text{Gal}(F/\mathbb{Q}) \) and \( \text{Gal}(K/\mathbb{Q}) \), which are cyclic by Proposition 16.5. Thus the previous isomorphism is a primary decomposition of the finite abelian group \( \text{Gal}(FK/F \cap K) \). However, \( \text{Gal}(FK/F \cap K) \) is cyclic of order a power of 2, being a subgroup of \( \text{Gal}(FK/\mathbb{Q}) \), which is cyclic by Proposition 16.5. The uniqueness of the primary decomposition of a finite abelian group ensures that \( \text{Gal}(F/F \cap K) \) or \( \text{Gal}(K/F \cap K) \) is trivial. Therefore \( F = F \cap K \) or \( K = F \cap K \), which implies in the first case that \( F \subset K \) and in the second that \( K \subset F \). As \( [F : \mathbb{Q}] = [K : \mathbb{Q}] \), we must have \( F = K \). \( \square \)

We have shown in the previous section that when the extension \( L/\mathbb{Q} \) is abelian of degree a power of \( p \), with \( p \) an odd prime, and \( \text{disc}(O_L) \) a power of \( p \), then there exists a root of unity \( \zeta \) such that \( L \subset \mathbb{Q}(\zeta) \). We will now establish an analogous result for the prime 2.

253
Theorem 16.3 Let $L/Q$ be a finite normal abelian of degree a power of 2, with $\text{disc}(O_L)$ a power of 2. Then there exists a root of unity $\zeta$ such that $L \subset Q(\zeta)$.

Proof In Proposition 16.6 we have already proved the theorem in the case where $L$ is a real field. Our aim is now to generalize this to any field contained in $C$.

Let $K = L(i) \cap R$. Then $K$ is a real extension of $Q$. As $L(i) = Q(i)L$ and both $Q(i)/Q$ and $L/Q$ are finite normal abelian extensions, $L(i)/Q$ is also a finite normal abelian extension (Theorem 6.10). Since $K$ is a subfield of $L(i)$, $K$ is a finite normal abelian extension of $Q$.

Next we notice that $[K : Q]$ is a power of 2. Indeed,

$$[L(i) : Q] = [L(i) : L][L : Q].$$

As $m(i, L)$ divides $f(X) = 1 + X^2$, the degree of $m(i, L)$ is 1 or 2 and so $[L(i) : L]$ is equal to 1 or 2. By hypothesis $[L : Q]$ is a power of 2, so $[L(i) : Q]$ is a power of 2. However, $[K : Q]$ divides $[L(i) : Q]$, hence $[K : Q]$ is a power of 2.

Our next step is to show that the discriminant $\text{disc}(O_K)$ is also a power of 2. If $q$ is a prime number dividing $\text{disc}(O_{L(i)})$, then $q$ divides $\text{disc}(O_{Q(i)})$ or in $L$ (Theorem 13.12), i.e., $q$ divides $\text{disc}(O_{Q(i)})$ or $q$ divides $\text{disc}(O_L)$. Now, by hypothesis $\text{disc}(O_L)$ is a power of 2, and $\text{disc}(O_{Q(i)}) = -4$, because $-1 \equiv 3 \pmod{4}$ implies that $\text{disc}(O_{Q(i)}) = 4(-1) = -4$. It follows that $q = 2$ and so $\text{disc}(O_{L(i)})$ is a power of 2. As $K$ is a subfield of $L(i)$, $\text{disc}(O_K)$ is also a power of 2. Indeed, if $q$ is a prime dividing $\text{disc}(O_K)$, then $q$ divides $\text{disc}(O_{L(i)})$ and so $q = 2$.

We now apply Proposition 16.6: there exists a root of unity $\zeta$ such that $K \subset Q(\zeta)$. From the primitive element theorem (Theorem 3.4), there exists $\alpha \in L(i)$ such that $L(i) = K(\alpha)$. Let $\alpha = a + ib$. As $\bar{\alpha} = a - ib$ is a root of the minimal polynomial $m(\alpha, K)$ and $L(i)$ is a normal extension of $K$, $a = \frac{2a+i\zeta}{2} \in K$ and $b = \frac{-a-i\zeta}{2} \in K$. Also, $i = \zeta_4$, so $\alpha = a + ib \in Q(\zeta_4)Q(\zeta)$. Then

$$L \subset L(i) = K(\alpha) \subset Q(\zeta_4)Q(\zeta) = Q(\zeta),$$

where $\xi$ is a root of unity, by Exercise 7.3.

Exercise 16.1 With $K$ and $L$ as defined in Theorem 16.3, show that $L(i) = K(i)$.

16.4 Step 3: $[L : Q]$ is a power of a prime $p$.

We have shown that a normal abelian extension $L$ of the rationals of degree a power of $p$ such that the discriminant $\text{disc}(O_L)$ is also a power of $p$ can be considered as a subfield of a cyclotomic extension of the rationals. In this section we aim to show that we may dispense with the condition on the discriminant. We will begin with a preliminary result.

Proposition 16.7 Suppose that $L/Q$ is a normal abelian extension of degree $n$ and $q$ a prime dividing $\text{disc}(O_L)$ but not dividing $n$. Then there exists a normal abelian extension $L'/Q$ and a primitive $q$th root of unity $\zeta$ such that

- $[L' : Q]$ divides $n$;
- $L \subset L'(\zeta)$;
- $q$ does not divide $\text{disc}(O_{L'})$;
- any prime $q'$ dividing $\text{disc}(O_{L'})$ also divides $\text{disc}(O_L)$.
PROOF We consider two cases, namely when $L$ contains a primitive $q$th root of unity and then when this is not the case.

**Case 1**: $L$ contains a primitive $q$th root of unity $\zeta$.

Suppose that $Q$ is a prime ideal in $O_L$, lying above $q$: $Q \cap \mathbb{Z} = \mathbb{Z}q$. To simplify the notation we write $e$ for the ramification index $e(Q|q)$, $V_1$ for the corresponding ramification group $V_1(Q|q)$ and $E$ for the corresponding inertia group $E(Q|q)$.

The assumption that $q$ does not divide $[L: Q]$ ensures that $L = L^{V_1}$. Indeed, from Proposition 13.18 we know that $V_1$ is a $q$-group, i.e., the order of $V_1$ is a power of $q$, thus Theorem 6.7 ensures that $[L: L^{V_1}]$ is a power of $q$. Moreover, $[L: L^{V_1}]$ divides $[L: Q]$. Since $q$ does not divide $[L: Q]$ we must have $[L: L^{V_1}] = 1$, i.e., $L = L^{V_1}$.

Now we consider $L^E$. As $L/Q$ is normal, by Proposition 13.11 we have $[L: L^E] = e$. Now, from Theorem 6.7 we obtain $Gal(L/L^E) = E$ and so

$$e = [L^{V_1}: L^E] = |E/V_1|,$$

by Theorem 6.6. Since $Gal(L/Q)$ is abelian, the decomposition group $D(Q|Zq)$, being a subgroup of $Gal(L/Q)$, is also abelian. Given that $L/Q$ is normal, Corollary 13.9 ensures that $|E/V_1|$ divides $q-1$, where

$$q' = |O_Q/Zq| = |Z/Zq| = q.$$

We now set $L' = L^E$. As $E$ is a subgroup of $Gal(L/Q)$, $[L' : Q]$ divides $n$. Also, $L'/Q$ is a normal abelian extension, because $L' = L^E$ and $E$ is a normal subgroup of $Gal(L/Q)$, which is abelian.

By hypothesis there is a primitive $q$th root of unity $\zeta$ in $L$. We claim that $L = L'\langle \zeta \rangle$. As $Q \subset L$ and $\zeta \in L$, we have $Q(\zeta) \subset L$. The prime ideal $Q$ in $O_L$ lies over a unique prime ideal $Q'$ in $O_Q(\zeta)$. To simplify the notation we write $e'$ for the ramification index $e(Q|Q')$ and $E'$ for the inertia group $E(Q|Q')$. We notice that $E' = E \cap Gal(L/Q(\zeta))$, the intersection of two subgroups of $Gal(L/Q)$. Using Theorem 6.9 we have

$$L^{E'} = L^E L^{Gal(L/Q(\zeta))} = L^E Q(\zeta) = L^E (\zeta) = L'(\zeta).$$

To establish the claim it is sufficient to show that $L^{E'} = L$. By Proposition 5.3 $L/Q(\zeta)$ is a normal extension, so we may use Proposition 13.11 to obtain $[L : L^{E'}] = e'$. Also,

$$e = e' e(Q'|q).$$

From equations (16.3) and (16.4) we obtain $e|q-1$. However, we also have $q-1|e$. From Theorem 11.15, $\text{disc}(O_Q(\zeta))$ is a power of $q$, so $q$ is totally ramified in $O_Q(\zeta)$, by Proposition 16.1, which implies that $e(Q'|q) = q-1$, because $[L^{\psi}(\zeta) : L^{\psi}(Q)] = q-1$. Therefore, by equation (16.5), $q-1|e$. It follows that $e = q-1$ and so $e' = 1$, which implies that $[L : L^{E'}] = 1$. We have shown that $L^{E'} = L$ and hence established the claim.

We now show that the remaining two conditions of the proposition are satisfied. First we show that $q$ does not divide $\text{disc}(O_L)$. Let $Q_1$ be a prime ideal of $O_L$, lying over $q$ and $Q_2$ a prime ideal in $O_L$ lying over $Q_1$. Both $Q_2$ and $Q$ are prime ideals in $O_L$ lying over $q$. As $Gal(L/Q)$ is abelian, Exercise 13.4 ensures that $E(Q_2|Zq) = E(Q|Zq)$. Hence $L' = L^{E(Q_2|Zq)}$. 

255
The ideal $Q_1$ is the unique prime ideal in $O_{L'} (=O_{L'})$ lying under $Q_2$, so, by Proposition 13.14, $e(Q_1)Z_1 = 1$, i.e., $q$ is unramified in $O_{L'}$, which implies that $q$ does not divide $\text{disc}(O_{L'})$.

Finally, we show that, if $q'$ is a prime dividing $\text{disc}(O_{L'})$, then $q'$ divides $\text{disc}(O_L)$. If $q'$ is a prime dividing $\text{disc}(O_{L'})$, then $q'$ ramifies in $O_{L'}$, which implies that $q'$ ramifies in $O_L$, because $L' \subset O_L$; hence $q'$ divides $\text{disc}(O_L)$. \hfill $\Box$

**Case 2:** $L$ does not contain a primitive $q$th root of unity.

We begin by adding a primitive $q$th root of unity $\zeta$ to $L$. We may apply Case 1 to $L(\zeta)$. Indeed, $L(\zeta) = LQ(\zeta)$. As both $L$ and $Q(\zeta)$ are normal extensions of $Q$, by Theorem 6.8, $LQ(\zeta)$ is a normal extension of $Q$. In addition, by Theorem 6.10, $\text{Gal}(LQ(\zeta)/Q)$ is a subset of $\text{Gal}(L/Q) \times \text{Gal}(Q(\zeta)/Q)$, hence abelian. By construction, $L(\zeta)$ contains a primitive $q$th root of unity. Moreover, $q$ divides $\text{disc}(O_{L(\zeta)})$, because $q$ divides $\text{disc}(O_L)$ and $O_L \subset O_{L(\zeta)}$. It remains to show that $q$ does not divide $[L(\zeta) : Q]$. As

$$[L(\zeta) : Q] = [L(\zeta) : L][L : Q],$$

if $q || [L(\zeta) : Q]$, then either $q || [L(\zeta) : L]$ or $q || [L : Q]$. By hypothesis, the second alternative is not possible. Also, by Theorem 7.4, the Galois group $\text{Gal}(L(\zeta)/L)$ is a subset of $\mathbb{Z}_q^\times$, which implies that $[L(\zeta) : L]|q - 1$. As $q$ does not divide $q - 1$, the second alternative is also not possible. We have shown that $q$ does not divide $[L(\zeta) : Q]$.

As all the conditions of Case 1, with $L$ replaced by $L(\zeta)$, are satisfied, there exists a finite normal extension $L'$ of $Q$ and a primitive $q$th root of unity $\xi$ such that

- $L(\zeta) \subset L'\xi$;
- $q$ does not divide $\text{disc}(O_{L'})$;
- any prime $q'$ dividing $\text{disc}(O_{L'})$ also divides $\text{disc}(O_{L(\zeta)})$.

As $L'(\zeta) = L'(\xi)$, we may suppose that $\xi = \zeta$. In the course of proving Case 1 we showed that $e = q - 1$, thus by Theorem 13.11 $[L : L^E] = q - 1$, i.e., $[L : L'] = q - 1$. Replacing $L$ by $L(\zeta)$ we obtain $[L(\zeta) : L'] = q - 1$. In a similar way, we obtain $L' \subset L(\zeta)$.

We maintain that $L'$ has the required properties of the proposition.

- $[L' : Q]$ divides $n = [L : Q]$: Using Corollary 6.1, we have

$$[L(\zeta) : Q] = [LQ(\zeta) : Q] = \frac{[L : Q][Q(\zeta) : Q]}{[L \cap Q(\zeta) : Q]} = \frac{[L : Q]([q - 1])}{[L \cap Q(\zeta) : Q]}.$$  

Thus

$$[L : Q][q - 1] = [L \cap Q(\zeta) : Q][L(\zeta) : L'][L' : Q],$$

which implies that

$$[L : Q] = [L \cap Q(\zeta) : Q][L' : Q],$$

- $L \subset L'(\zeta)$, since $L \subset L(\zeta) \subset L'(\zeta)$.
- $q$ does not divide $\text{disc}(O_{L'})$: Here there is nothing to prove.
We are now in a position to prove the general case of the Kronecker-Weber theorem.

Theorem 16.4 If $L/Q$ is a normal abelian extension of degree $p^m$, for some prime $p$, then there exists a root of unity $\zeta$ such that $L \subset Q(\zeta)$.

Proof If the discriminant $\text{disc}(O_L)$ is also a power of $p$, then there is nothing to prove, so let us suppose that this is not the case. Then there is a prime $q \neq p$ dividing the discriminant. From Proposition 16.7 there is an abelian extension $L_1/Q$ and a $q$th root of unity $\zeta_1$ such that

- $[L_1 : Q]$ divides $p^m$ and so is a power of $p$;
- $L \subset L_1(\zeta_1)$;
- $q$ does not divide $\text{disc}(O_{L_1})$;
- any prime $q'$ dividing $\text{disc}(O_{L_1})$ also divides $\text{disc}(O_L)$.

Thus $\text{disc}(O_{L_1})$ has fewer prime factors than $\text{disc}(O_L)$. We can repeat the process and so find a normal abelian extension $L_2/Q$ and a root of unity $\zeta_2$ such that $L_1 \subset L_2(\zeta_2)$, $[L_2 : Q]$ is a power of $p$ and $\text{disc}(O_{L_2})$ has fewer prime factors than $\text{disc}(O_{L_1})$. Continuing in the same way, we finally obtain a normal abelian extension $L_r/Q$ and a root of unity $\zeta_r$ such that $L_{r-1} \subset L_r(\zeta_r)$, $[L_r : Q]$ is a power of $p$ and $\text{disc}(O_{L_r})$ is also a power of $p$, possibly 1, in which case $L_r = Q$ (Theorem 13.12). It follows from Theorems 16.2 and 16.3 that there is a root of unity $\zeta_{r+1}$ such that $L_r \subset Q(\zeta_{r+1})$. To sum up, we have the inclusions

$$L \subset L_1(\zeta_1), L_1 \subset L_2(\zeta_2), \ldots, L_{r-1} \subset L_r(\zeta_r), L_r \subset Q(\zeta_{r+1}),$$

which implies that

$$L \subset Q(\zeta_1, \zeta_2, \ldots, \zeta_{r+1}) \subset Q(\zeta),$$

where $\zeta$ is a root of unity (Exercise 7.3). This ends the proof.

16.5 Step 4: The general case

We are now in a position to prove the general case of the Kronecker-Weber theorem.

Theorem 16.5 If $L/Q$ is a finite normal abelian extension, then there is a primitive root of unity $\zeta$ such that $L \subset Q(\zeta)$.

Proof As $\text{Gal}(L/Q)$ is abelian, there exist prime numbers $p_1, \ldots, p_s$ and $p_i$-subgroups $H_1, \ldots, H_s$ such that

$$\text{Gal}(L/Q) \simeq H_1 \times \cdots \times H_s.$$
If $|H| = p_i^\alpha_i$, then $|\text{Gal}(L/Q) = \prod_{i=1}^s p_i^\alpha_i$. Let $\hat{H}_j = \prod_{i \neq j} H_i$ and $L_j = L^{\hat{H}_j}$. Then $[L_j : Q] = p_j^\alpha_j$. Moreover, since $L/Q$ is assumed normal, Theorem 6.9 ensures that 

$$L^{\bigcap_{i=1}^s \hat{H}_i} = \prod_{i=1}^s L^{\hat{H}_i} = \prod_{i=1}^s L_i.$$ 

Since $\bigcap_{i=1}^s \hat{H}_i = \{e\}$, we obtain $\prod_{i=1}^s L_i = L$. Also, each subgroup $\hat{H}_i$ is normal in $\text{Gal}(L/Q)$, so, by Theorem 6.6, $L_i/Q$ is normal and $\text{Gal}(L_i/Q) \cong \text{Gal}(L/Q)/\hat{H}_i$. Therefore $L_i/Q$ is a finite normal abelian extension, with degree a power of a prime, and so there exists a root of unity $\zeta_i$ such that $L_i \subset Q(\zeta_i)$. Thus 

$$L = L_1 \cdots L_s \subset Q(\zeta_1) \cdots Q(\zeta_s) \subset Q(\zeta),$$ 

where $\zeta$ is a primitive root of unity (Exercise 7.3), i.e., $L$ is included in a cyclotomic extension of $Q$. \hfill $\square$

The Kronecker-Weber theorem answers an important question. Earlier we saw that a cyclotomic extension of the rationals is normal and abelian; it follows that any subextension of a cyclotomic extension of the rationals is also normal and abelian. It is natural to ask whether there are other finite normal abelian extensions of the rationals. The Kronecker-Weber theorem gives a negative response to this question.
Chapter 17

Factoring primes in extensions

In a unique factorization domain \(R\) any element \(x\) which is neither the identity for the addition nor a unit can be expressed as product of prime factors and a unit: \(x = u p_1^{a_1} \cdots p_n^{a_n}\), where \(u\) is a unit and \(p_1, \ldots, p_n\) are prime factors, which are not associated. There may be different such factorizations, but the number \(n\) is always the same, as are the powers \(a_1, \ldots, a_n\). If we take the powers of the primes in increasing order, then we obtain a finite sequence of positive integers, which we call the form of the decomposition. For example, \(12 = 3 \cdot 2^2\), so the form of the decomposition of \(12\) is \((1, 2)\). Similarly, \(30 = 2 \cdot 3 \cdot 5\) has the form \((1, 1, 1)\), \(36 = 2^2 \cdot 3^2\) the form \((2, 2)\) and \(20 = 5 \cdot 2^2\) the form \((1, 2)\). We should notice that the factorizations of \(12\) and \(20\) have the same form \((1, 2)\); thus different elements may have factorizations with the same form.

If \(K\) is a number field and \(O_K\) its number ring, then any nonzero ideal of \(O_K\) not equal to \(O_K\) has a unique factorization into prime ideals, because \(O_K\) is a Dedekind domain. For a prime number \(p\) we will be concerned in this chapter with the form of the factorization of the ideal \(O_K p\).

17.1 Preliminary results

**Proposition 17.1** Let \(K\) be a number field of degree \(n\) over \(Q\) and \(R\) an order of \(O_K\). Then

\[
|\text{disc}(R)| = |O_K : R|^2 |\text{disc}(O_K)|,
\]

where \([O_K : R]\) is the index of \(R\) as an additive subgroup of \(O_K\).

**Proof** We argue as in Section 14.1, defining \(\phi\) in the same way. If \(B = (\beta_1, \ldots, \beta_n)\) is a basis of \(R\), then \(B' = (\phi(\beta_1), \ldots, \phi(\beta_n))\) generates \(\phi(R)\) over \(Z\) and is an independent set, hence \(\phi(R)\) is a sublattice of \(\Lambda_{O_K}\), which we note \(\Lambda_R\). We have

\[
[\Lambda_{O_K} : \Lambda_R] = \frac{\det \Lambda_R}{\det \Lambda_{O_K}} \implies \det \Lambda_{O_K} [\Lambda_{O_K} : \Lambda_R] = \det \Lambda_R.
\]

However, from Section 14.1 we have

\[
\det \Lambda_{O_K} = 2^{-s} \sqrt{|\text{disc}(O_K)|} \quad \text{and} \quad \det \Lambda_R = 2^{-s} \sqrt{|\text{disc}(R)|},
\]

hence

\[
|\text{disc}(R)| = |O_K : R|^2 |\text{disc}(O_K)|.
\]
because $[\Lambda_{O_K} : \Lambda_R] = [O_K : R]$. 

A particular application of this result is when $\alpha \in O_K$, $K = \mathbb{Q}(\alpha)$ and $R = \mathbb{Z}[\alpha]$. In this case the elements $1, \alpha, \ldots, \alpha^{n-1}$ form an integral basis of $\mathbb{Z}[\alpha]$. As we will see presently, it is often important to know whether a given prime number $p$ does not divide $[O_K : \mathbb{Z}[\alpha]]$. In particular, if the discriminant $\text{disc}(\mathbb{Z}[\alpha])$ is square-free, then $[O_K : \mathbb{Z}[\alpha]] = 1$ and so $\mathbb{Z}[\alpha] = O_K$.

In fact, we may improve the equality of Proposition 17.1.

**Lemma 17.1** Let $K$ be a number field such that $[K : \mathbb{Q}] = n$. We suppose that there are $r$ real embeddings of $K$ in $\mathbb{C}$ and $2s$ complex embeddings. Then the sign of the discriminant of an order $R$ in $K$ is $(-1)^s$.

**Proof** Let $B = \{b_1, \ldots, b_n\}$ be an integral basis of $R$. Then
\[
\text{disc}(R) = \det(\sigma_i(b_j))^2,
\]
where $\sigma_1, \ldots, \sigma_r$ are the real embeddings of $K$ into $\mathbb{C}$ and $\sigma_{r+1}, \ldots, \sigma_{r+2s}$ the complex embeddings of $K$ into $\mathbb{C}$. We have
\[
\det(\sigma_i(b_j)) = (-1)^s \det(\sigma_i(b_j)),
\]
because complex conjugation interchanges $s$ rows. If $s$ is even, then $\det(\sigma_i(b_j))$ is real, so its square is positive. On the other hand, if $s$ is odd, then $\det(\sigma_i(b_j))$ is purely imaginary, so its square is negative.

We may now improve Proposition 17.1:

**Theorem 17.1** Let $K$ be a number field of degree $n$ over $\mathbb{Q}$ and $R$ an order of $O_K$. Then
\[
\text{disc}(R) = \left[O_K : R\right]^2 \text{disc}(O_K),
\]
where $[O_K : R]$ is the index of $R$ as an additive subgroup of $O_K$.

**Proof** From Lemma 17.1 the discriminants of both $R$ and $O_K$ have the sign $(-1)^s$. 

We also need some elementary results from group theory.

**Lemma 17.2** Let $G$ be a finite (additive) abelian group of order $n$. If $p$ is a prime and $p$ does not divide $n$, then the mapping
\[
\phi : G \rightarrow G, x \mapsto px
\]
is an automorphism.

**Proof** The mapping $\phi$ is clearly a homomorphism. As $G$ is finite, it is sufficient to show that $\phi$ is injective. Suppose that $px = 0$. If $x \neq 0$, then $1 < o(x) \leq p$, which implies that $o(x) = p$. Then we have $p|n$, a contradiction. So $\phi$ is injective. 

**Proposition 17.2** Let $\psi : G' \rightarrow G$ be an injective homomorphism of (additive) abelian groups. If $H = \psi(G')$ and $\left|\frac{G}{H}\right|$ is finite and not divisible by the prime $p$, then the induced mapping
\[
\tilde{\psi} : \frac{G'}{pG'} \rightarrow \frac{G}{pG} : x' \mapsto \psi(x') + pG
\]
is an isomorphism.

260
PROP Let $\psi$ be a homomorphism. From Lemma 17.2 the mapping

$$\psi : \frac{G}{H} \rightarrow \frac{G}{H}, x + H \mapsto px + H$$

is an automorphism. If $x \in G$, then there exists $x_1 \in G$ such that

$$x + H = px_1 + H \implies x - px_1 \in H \implies x - px_1 = \psi(x'),$$

with $x' \in G'$. Then

$$x + pG = px_1 + \psi(x') + pG = \psi(x') + pG = \psi(x' + pG'),$$

so $\tilde{\psi}$ is surjective.

We now show that $\tilde{\psi}$ is injective. Let $x' + pG' \in \frac{G'}{pG'}$ be such that $\tilde{\psi}(x' + pG') = 0$, i.e., $\psi(x') \in pG$. Then there exists $x_1 \in G$ such that $\psi(x') = px_1$. We now set $x = \psi(x') = px_1$. Then $x \in H \cap pG$. Now

$$p(x_1 + H) = px_1 + H = x + H = H = 0.$$}

From Lemma 17.2 the mapping $\psi$ is an automorphism, hence $x_1 + H = H$, which implies that $x_1 \in H$. Thus we may write $x_1 = \psi(x'_1)$, with $x'_1 \in G'$. We have

$$x = \psi(x') \quad \text{and} \quad x = px_1 = p\psi(x'_1) = \psi(px'_1),$$

which implies that $x' = px'_1$, because $\psi$ is injective. This shows that $x' \in pG'$ and so $x' + pG' = 0$. It follows that $\psi$ is injective. \qed

### 17.2 Dedekind’s factorization theorem

In the following discussion which will lead to Dedekind’s factorization theorem we will use some general results from ring theory. Let us begin with these results.

**Proposition 17.3** If $f : R \rightarrow S$ is a surjective ring homomorphism, then the inverse image of a maximal ideal $M$ in $S$ is maximal. If $N$ is a maximal ideal in $R$, then its image in $S$ is either $S$ or a maximal ideal.

**Proposition 17.4** If $I$ and $J$ are coprime ideals in a commutative ring $R$ and $m, n \in \mathbb{N}^*$, then $I^m$ and $J^n$ are coprime.
From Proposition 17.2, the natural ring inclusion isomorphism

\[ \overline{\pi} \] is surjective when restricted to maximal ideals. As \( \overline{\pi} \) deduce that

\[ x \in \mathcal{O} \text{ containing } \mathcal{O} \]

is an ideal in \( \mathcal{O} \) of a prime number in a number ring. Let \( \mathcal{R}/N \) field \( N \) of \( \mathcal{R}/I \). If restricted to prime (resp. maximal) ideals, then we obtain a bijection of the set of prime (resp. maximal) ideals containing \( I \) onto the set of prime (resp. maximal) ideals in \( \mathcal{R}/I \).

\[ I \]

Let \( A \) be the set of ideals in \( \mathcal{R} \) containing \( I \) and \( B \) the set of ideals in \( \mathcal{R}/I \). Using the fact that \( \pi \) is a surjective homomorphism, there is no difficulty in seeing that \( \overline{\pi} \) defines a mapping from \( A \) into \( B \), which we will write \( \overline{\pi} \). If \( J \in B \), then \( \pi^{-1}(J) \) is an ideal in \( \mathcal{R} \) and \( \pi(\pi^{-1}(J)) = J \), so \( \overline{\pi} \) is surjective.

Suppose now that there exist ideals \( I_1, I_2 \) containing \( I \) such that \( \overline{\pi}(I_1) = \overline{\pi}(I_2) \), i.e., \( \overline{I_1} = \overline{I_2} \). If \( s \in I_1 \), then \( s + I = t + I \), for some \( t \in I_2 \). Hence there exist \( x_1, x_2 \in I \) such that \( s + x_1 = t + x_2 \), which implies that \( s = t + x_2 - x_1 \in I_2 \). Thus \( I_1 \subseteq I_2 \). In the same way; \( I_2 \subseteq I_1 \), so \( I_1 = I_2 \) and \( \overline{\pi} \) is injective.

Now let us restrict \( \overline{\pi} \) to prime ideals. If \( P \) is a prime ideal, then it is easy to see that \( \pi(P) \) is a prime ideal in \( \mathcal{R}/I \). Suppose that \( Q \) is a prime ideal in \( \mathcal{R}/I \); then \( \pi^{-1}(Q) \) is a prime ideal in \( \mathcal{R} \) containing \( I \) and \( \pi(\pi^{-1}(Q)) = Q \). Thus \( \overline{\pi} \) as a mapping from the prime ideals containing \( I \) into the prime ideals in \( \mathcal{R}/I \) is surjective. Since \( \overline{\pi} \) is injective, the mapping \( \overline{\pi} \) must be injective when restricted to prime ideals.

Finally let us consider maximal ideals. Let \( N \) be a maximal ideal in \( \mathcal{R} \) containing \( I \). We claim that \( \overline{\pi}(N) \) is properly contained in \( \mathcal{R}/I \). If \( \overline{\pi}(N) = \mathcal{R}/I \), then, for any \( r \in \mathcal{R} \), there exists \( x \in N \) such that \( r - x \in I \). Thus \( r \in N \), because \( N \) contains \( I \); this implies that \( \mathcal{R} = N \), which is not possible, because \( N \) is a maximal ideal in \( \mathcal{R} \). Thus \( \overline{\pi}(N) \neq \mathcal{R}/I \). From Proposition 17.3 we deduce that \( \overline{\pi}(N) \) is a maximal ideal in \( \mathcal{R}/I \). Hence \( \overline{\pi} \) takes maximal ideals to maximal ideals.

If \( M \) is a maximal ideal in \( \mathcal{R}/I \), then \( \pi^{-1}(M) \) is a maximal ideal in \( \mathcal{R} \) and \( \pi(\pi^{-1}(M)) = M \), so \( \overline{\pi} \) is surjective when restricted to maximal ideals. As \( \overline{\pi} \) is injective, \( \overline{\pi} \) is injective when restricted to maximal ideals.

Exercise 17.1 Let \( I \) be an ideal in the commutative ring \( \mathcal{R} \) and \( \pi \) the canonical projection of \( \mathcal{R} \) onto \( \mathcal{R}/I \). If \( M \) is a maximal ideal in \( \mathcal{R}/I \), then we know that there is a unique maximal ideal \( N \) of \( \mathcal{R} \) containing \( I \) such that \( \pi(N) = M \). Show that the field \( (\mathcal{R}/I)/M \) is isomorphic to the field \( \mathcal{R}/N \).

The principle result which we will establish in this section enables us, in all but a finite number of cases, to find the form of the factorization into prime ideals of an ideal which is the extension of a prime number in a number ring. Let \( K \) be a number field with associated number ring \( O_K, \alpha \in O_K \) and \( K = \mathcal{Q}(\alpha) \). We suppose that \( p \) is a prime which does not divide \( [O_K : \mathcal{Z}[\alpha]] \). From Proposition 17.2, the natural ring inclusion \( \psi \) of \( \mathcal{Z}[\alpha] \) into \( O_K \) induces an additive group isomorphism

\[ \psi: \mathcal{Z}[\alpha] \rightarrow O_K \]

\[ \mathcal{Z}[\alpha]/p \rightarrow O_K/p \]

There is no difficulty in seeing that \( \psi \) is also a ring isomorphism.

It is worth studying the mapping \( \psi \) in more detail. If \( I \) is an ideal in \( \mathcal{Z}[\alpha]/p \), then its image is an ideal in \( O_K/p \). However, there is an additional difficulty. The ideal \( I \) is of the form \( \mathcal{Z}[\alpha]/p \mathcal{R}_{\mathcal{K} p} \), where \( I \) is an ideal containing \( \mathcal{Z}[\alpha]/p \mathcal{Z}[\alpha] \) and \( \psi(I) = \mathcal{R}_{\mathcal{K} p} \) is composed of the classes of \( \mathcal{R}_{\mathcal{K} p} \) having a

262
representative in \( I \). At first viewing it is not clear how \( \frac{I}{O_{KP}} \) can be an ideal in \( \frac{O_K}{O_{KP}} \). In particular, when we multiply an element in \( \frac{I}{O_{KP}} \) by an element in \( \frac{O_K}{O_{KP}} \), how can we be sure that the result lies in \( I + O_{KP} \)? This in fact is the case. We consider the case

\[
(a + O_{KP})(x + O_{KP})
\]

where \( a \in O_K \) and \( x \in I \). As \( \tilde{\psi} \) is bijective, there exists \( a' \in \mathbb{Z}[\alpha] \) such that \( a + O_{KP} = a' + O_{KP} \). Hence we may write

\[
(a + O_{KP})(x + O_{KP}) = (a' + O_{KP})(x + O_{KP}) = a'x + O_{KP} \in \frac{I}{O_{KP}},
\]

which resolves the apparent problem.

The mapping \( \tilde{\psi} \) provides us with a bijection from the set of ideals in \( \mathbb{Z}[\alpha]/Z_{\alpha}[p] \) onto the set of ideals in \( \frac{O_K}{O_{KP}} \) and maps a prime ideal to a prime ideal. We may find an interesting expression for the image of an ideal in \( \mathbb{Z}[\alpha]/Z_{\alpha}[p] \). First \( \tilde{\psi}(\frac{I}{O_{KP}}) = \frac{I}{O_{KP}} \). As \( I \subset O_{KI} \), we have \( \frac{I}{O_{KP}} \subset \frac{O_{KI}}{O_{KP}} \).

Now let \( u \in \frac{O_{KI}}{O_{KP}} \). Then we may write \( u = \sum_{i=1}^{s} a_i x_i + O_{KP} \) with \( a_i \in O_K \), \( x_i \in I \). As above, for each \( a_i \), there exists \( a'_i \in \mathbb{Z}[\alpha] \) such that \( a_i + O_{KP} = a'_i + O_{KP} \), thus

\[
\sum_{i=1}^{s} a_i x_i + O_{KP} = \sum_{i=1}^{s} (a_i + O_{KP})(x_i + O_{KP}) = \sum_{i=1}^{s} (a'_i + O_{KP})(x_i + O_{KP}) = \sum_{i=1}^{s} a'_i x_i + O_{KP}.
\]

As \( a'_i x_i \in I \), for each \( i \), we see that \( u \in \frac{I}{O_{KP}} \). It follows that \( \frac{O_{KI}}{O_{KP}} \subset \frac{I}{O_{KP}} \). Thus for an ideal \( \frac{I}{Z_{\alpha}[p]} \) in \( \mathbb{Z}[\alpha]/Z_{\alpha}[p] \), we have \( \tilde{\psi}(\frac{I}{Z_{\alpha}[p]}) = \frac{O_{KI}}{O_{KP}} \).

**Remark** The mapping \( \tilde{\psi} \) enables us to define a bijection between prime ideals containing \( p \) in \( \mathbb{Z}[\alpha] \) and prime ideals in \( O_K \) containing \( p \). Let \( \pi_1 \) be the projection of \( \mathbb{Z}[\alpha] \) onto \( \mathbb{Z}[\alpha][p] \) and \( \pi_2 \) the projection of \( O_K \) onto \( O_{KP} \). If \( P \) is a prime ideal in \( \mathbb{Z}[\alpha] \) containing \( a \) (or, equivalently \( \mathbb{Z}[\alpha][p] \)), then, from Proposition 17.5, \( \pi_1(P) = \frac{P}{\mathbb{Z}[\alpha][p]} \) is a prime ideal in \( \mathbb{Z}[\alpha]/\mathbb{Z}[\alpha][p] \). As \( \tilde{\psi} \) is an isomorphism, \( \tilde{\psi}(\frac{P}{\mathbb{Z}[\alpha][p]}) \) is a prime ideal in \( \frac{O_K}{O_{KP}} \), i.e., \( \frac{O_{KP}}{O_{KP}} \) is a prime ideal in \( \frac{O_K}{O_{KP}} \). Then \( O_K P = \pi_2^{-1}(\frac{O_K P}{O_{KP}}) \) is a prime ideal in \( O_K \) containing \( O_{KP} \) (or, equivalently \( p \)). Thus the mapping \( P \mapsto O_K P \) sends prime ideals in \( \mathbb{Z}[\alpha] \) containing \( p \) to prime ideals in \( O_K \) containing \( p \). Since \( O_K P = \pi_2^{-1}(\tilde{\psi}(\pi(P))) \), this mapping is a bijection. We should also notice that it is multiplicative, i.e., if \( I, J \) are ideals in \( \mathbb{Z}[\alpha] \) such that \( p \in I, p \in J \) and \( p \in IJ \), then \( O_K(IJ) = (O_K I)(O_K J) \).

We now study the quotient ring \( \frac{\mathbb{Z}[\alpha]}{\mathbb{Z}[\alpha][p]} \) in more detail. We write \( \bar{g} \) for the polynomial \( g \in \mathbb{Z}[X] \) reduced modulo \( p \).

Let \( h \) be the minimal polynomial \( m(\alpha, Q) \). By Corollary 11.1, \( h \) belongs to \( \mathbb{Z}[X] \). The mapping \( e_a : \mathbb{Z}[X] \rightarrow \mathbb{Z}[\alpha] \) defined by \( e_a(g) = g(\alpha) \) is a surjective ring homomorphism. As \( h \) is monic and \( h(\alpha) = 0 \), the kernel of \( \phi \) is the ideal \( (h) \). It follows that the mapping

\[
e_a : \mathbb{Z}[X]/(h) \rightarrow \mathbb{Z}[\alpha], g + (h) \mapsto g(\alpha)
\]

263
is an isomorphism. We set \( \Psi = e^{-1}_\alpha \). Notice that, for \( a \in \mathbb{Z} \subseteq \mathbb{Z}[\alpha] \), we have \( \Psi(a) = a + (h) \).

**Proposition 17.6** We have

\[
\frac{\mathbb{Z}[\alpha]}{\mathbb{Z}[\alpha]p} \cong \frac{\mathbb{F}_p[X]}{(h)}.
\]

**Proof** First we notice that the image of the ideal \( \mathbb{Z}[\alpha]p \) under \( \Psi \) can be written \( \mathbb{Z}[X]p \mathbb{Z}[\alpha]p \), so we obtain an isomorphism \( \Psi \) from \( \mathbb{Z}[\alpha]p \) onto \( \mathbb{Z}[X]p \mathbb{Z}[\alpha]p / (h) \). We now consider the mapping

\[
\delta : \frac{\mathbb{Z}[X]}{(h)} \rightarrow \frac{\mathbb{Z}[X]}{(h)}, \quad (g + (h)) \mapsto (f + (h) + (h)) \mapsto \bar{g} + (h).
\]

The mapping \( \delta \) is clearly a surjective ring homomorphism. We need to show that \( \delta \) is also injective. If \( f \in (h) \), then there exists \( u \in \mathbb{Z}[X] \) such that \( f = uh - uh \). Thus \( f - uh \) is a polynomial in \( \mathbb{Z}[X] \), all of whose coefficients are multiples of \( p \), i.e., \( f - uh \in \mathbb{Z}[X]p \). Then

\[
f + (h) = (f - uh) + (h) \in \mathbb{Z}[X]p / (h) \quad \implies (f + (h)) = 0 \quad \text{in} \quad \frac{\mathbb{Z}[X]}{(h)} / \mathbb{Z}[X]p / (h).
\]

Hence \( \delta \) is injective and so we have the required isomorphism, namely \( \eta = \delta \circ \Psi \). Explicitly \( \eta \) maps \( g(\alpha) + \mathbb{Z}[\alpha]p \) to \( \bar{g} + (h) \).

**Remark** The image of \( \mathbb{Z}[\alpha]p \) is \( (h) \). \( \square \)

**Corollary 17.1** If \( p \) is a prime which does not divide \( [O_K : \mathbb{Z}[\alpha]] \), then the rings \( \frac{O_K}{\mathbb{Z}[\alpha]p} \) and \( \frac{\mathbb{F}_p[X]}{(h)} \) are isomorphic.

Now let us turn to Dedekind’s theorem. We first consider the prime ideals in \( \frac{\mathbb{F}_p[X]}{(h)} \). From Proposition 17.5 the prime ideals in \( \frac{\mathbb{F}_p[X]}{(h)} \) are of the form \( I / (h) \), where \( I \) is a prime ideal in \( \mathbb{F}_p[X] \) containing \( (h) \). As \( \mathbb{F}_p[X] \) is a PID, every ideal \( I \) is principal, i.e., \( I = (f) \) for some \( f \in \mathbb{F}_p[X] \). If \( (f) \) is an ideal containing \( (h) \), then \( f \) divides \( h \). Moreover, if \( (f) \) is a prime ideal, then \( f \) is a prime element. Given that a PID is a UFD, \( f \) must be an irreducible polynomial. Hence we are looking for irreducible polynomials in \( \mathbb{F}_p[X] \) dividing \( h \). If \( h = A_1 \cdots A_s \) is the factorization of \( h \) into irreducible polynomials in \( \mathbb{F}_p[X] \), then the \( A_i \) are the irreducible polynomials we are looking for. Hence the prime ideals in \( \frac{\mathbb{F}_p[X]}{(h)} \) are of the form \( (A_i) / (h) \). As the \( (A_i) \) are maximal ideals, so are the \( (A_i) / (h) \).

Our next step is to consider prime ideals in \( \mathbb{Z}[\alpha] / \mathbb{Z}[\alpha]p \). The inverse image of the mapping \( \eta \) defined in Proposition 17.6 is given by the evaluation at \( \alpha \), namely, if \( f \in \mathbb{F}_p[X] \) and \( g \in \mathbb{Z}[X] \) is such that \( \bar{g} = f \), then the preimage of \( f + (h) \) is \( g(\alpha) + \mathbb{Z}[\alpha]p \). (There is no difficulty in seeing that, if \( g, g_1 \in \mathbb{Z}[X] \) and \( \bar{g} = \bar{g}_1 \), then \( g(\alpha) + \mathbb{Z}[\alpha]p = g_1(\alpha) + \mathbb{Z}[\alpha]p \). In particular, if \( (f) \) is an ideal in \( \mathbb{F}_p[X] \) containing \( (h) \), then \( (f) / (h) \) is an ideal in \( \mathbb{Z}[\alpha]p / (h) \) and its preimage is \( \frac{\mathbb{Z}[\alpha]}{Z[\alpha]p} \). Clearly, if \( (f) \) is a prime ideal, then so is \( (f) / (h) \).

For each \( A_i \), let \( h_i \in \mathbb{Z}[X] \) be such that \( h_i = A_i \). For \( i = 1, \ldots, s \), we set \( \bar{P}_i = \eta^{-1}((A_i) / (h)) = \frac{((h), (\alpha))}{\mathbb{Z}[\alpha]p} \). The \( \bar{P}_i \) are the prime ideals in \( \frac{\mathbb{Z}[\alpha]}{\mathbb{Z}[\alpha]p} \). As the \( \bar{P}_i \) correspond to maximal ideals in \( \frac{\mathbb{F}_p[X]}{(h)} \), they are also maximal.

Let \( \pi \) be the natural projection of \( \mathbb{Z}[\alpha] \) onto \( \mathbb{Z}[\alpha]p / (h) \). Then \( \bar{P}_i = \pi^{-1}(\bar{P}_i) \) is a prime ideal in \( \mathbb{Z}[\alpha] \) containing \( \mathbb{Z}[\alpha]p \) (or, equivalently, containing \( p \)). From Proposition 17.5, we know that these are

264
the only prime ideals in \( \mathbb{Z}[\alpha] \) containing \( \mathbb{Z}[\alpha]p \). Setting \( Q_i = O_K P_i \), for \( i = 1, \ldots, s \), we obtain the prime ideals in \( O_K \) containing \( p \). The fact that \( Q_i \) contains \( p \) may be written \( Q_i | O_K p \). Thus the decomposition of \( O_K p \) into prime ideals has the form

\[
O_K p = Q_1^{e_1} \cdots Q_s^{e_s},
\]

where \( e'_i \) is the ramification index of \( Q_i \). We aim to show that \( e'_i = e_i \).

To begin with, we show that \( e'_i \leq e_i \). We claim that \((\pi^{-1}(\bar{P}))^{e_i} \subset \pi^{-1}(P_i^{e_i}) \). Let \( u \in (\pi^{-1}(\bar{P}))^{e_i} \). Then \( u \) is a finite sum of products of the form \( a_1 \cdots a_e \), such that \( \pi(a_1), \ldots, \pi(a_e) \in \bar{P} \). Suppose, for example, that \( u = a_1 \cdots a_e + b_1 \cdots b_e \). Then

\[
\pi(a_1) \cdots \pi(a_e) + \pi(b_1) \cdots \pi(b_e) \in \bar{P}^{e_i} \implies \pi(a_1 \cdots a_e + b_1 \cdots b_e) \in \bar{P}^{e_i} \implies u \in \pi^{-1}(P_i^{e_i}).
\]

The other cases, with more or less products in the sum, can be handled in an analogous way, hence \((\pi^{-1}(\bar{P}))^{e_i} \subset \pi^{-1}(P_i^{e_i}) \), as claimed.

We now consider the intersection \( \cap_{i=1}^s \pi^{-1}(P_i^{e_i}) \). Let \( u \in \cap_{i=1}^s \pi^{-1}(P_i^{e_i}) \). For \( i = 1, \ldots, s \), we have

\[
\pi(u) \in \left( \frac{h^{e_i}(\alpha)}{Z[\alpha]p} \right) \implies \eta(\pi(u)) \in \left( \frac{h^{e_i}}{h} \right),
\]

and so \( \eta(\pi(u)) = 1 \), which in turn implies that \( \pi(u) = \frac{Z[\alpha]p}{Z[\alpha]p} \). Therefore, \( u \in Z[\alpha]p \) and it follows that \( \cap_{i=1}^s \pi^{-1}(P_i^{e_i}) \subset Z[\alpha]p \). From this and the preceding paragraph we obtain

\[
Z[\alpha]p \supset \cap_{i=1}^s \pi^{-1}(P_i^{e_i}) \supset \cap_{i=1}^s \pi^{-1}(\bar{P}_i)^{e_i} = \cap_{i=1}^s P_i^{e_i}.
\]

We claim that \( \cap_{i=1}^s P_i^{e_i} = \prod_{i=1}^s P_i^{e_i} \). In the light of Proposition 12.4, it is sufficient to show that the ideals \( P_i^{e_i} \) are coprime, when \( i \neq j \). First, \( \pi \) is a surjective homomorphism and, for each \( i \), the ideal \( \bar{P}_i \) is maximal, so \( P_i \) is a maximal ideal from Lemma 17.3. It follows that \( P_i \) and \( P_j \) are coprime, when \( i \neq j \). Now, from Lemma 17.4, \( P_i^{e_i} \) and \( P_j^{e_j} \) are coprime and thus we obtain

\[
Z[\alpha]p \supset \prod_{i=1}^s P_i^{e_i}.
\]

Therefore

\[
O_K p \supset O_K \left( \prod_{i=1}^s P_i^{e_i} \right) = \prod_{i=1}^s Q_i^{e_i},
\]

This implies that \( e'_i \leq e_i \), for \( i = 1, \ldots, s \), as \( O_K p = \prod_{i=1}^s Q_i^{e_i} \).

We now show that \( e'_i = e_i \), for all \( i \). We need to consider the inertial degree \( f_i = f(Q_i|p) \), i.e., the degree of the extension \( \frac{Q_i}{Q_i p} \) over \( F_p \). We notice that the mapping

\[
f : \frac{Z}{Zp} \longrightarrow \frac{O_K}{Q_i}, \ a + Zp \longmapsto a + Q_i
\]

is a monomorphism, so \( \frac{Q_i}{Q_i p} \) is a field containing \( F_p \). Now, we have the following chain of additive group isomorphisms:

\[
\frac{O_K}{Q_i} \cong \frac{O_K}{O_K p} \cdot \frac{Q_i}{O_K p} \cong \frac{Z[\alpha]}{Z[\alpha] p} \cdot \frac{P_i}{Z[\alpha] p} = \frac{Z[\alpha]}{Z[\alpha] p} \cdot \frac{\bar{P}_i}{(h)} = \frac{F_p [X]}{(h)} \cdot \frac{(A_i)}{(A_i)} \cong \frac{F_p [X]}{(A_i)}.
\]
These spaces are also $\mathbf{F}_p$-vector spaces and it is not difficult to see that the additive group isomorphisms are also $\mathbf{F}_p$-vector space isomorphisms. Therefore the dimension of the field $\frac{\mathbf{Q}}{\mathbf{Q}_p}$ over $\mathbf{F}_p$ is that of $\frac{\mathbf{F}_p[X]}{(A_i)}$ over $\mathbf{F}_p$. This vector space has the dimension $d_i$, the degree of the polynomial $A_i$: If $f \in \mathbf{F}_p[X]$, then there exist $g, r_i \in \mathbf{F}_p[X]$ such that: $\deg (r_i) < d_i$ and $f = gA_i + r_i$. Then

$$f + (A_i) = gA_i + r_i + (A_i) = r_i + (A_i)$$

and it follows that $B = \{1 + (A_i), X + (A_i), \ldots, X^{d_i-1} + (A_i)\}$ is a generating set of $\frac{\mathbf{F}_p[X]}{(A_i)}$. $B$ is also an independent set. Let

$$\lambda_0(1 + (A_i)) + \lambda_1(X + (A_i)) + \cdots + \lambda_{d_i-1}(X^{d_i-1} + (A_i)) = (A_i),$$

where the $\lambda_i \in \mathbf{F}_p$. Then $U(X) = \sum_{j=0}^{d_i-1} \lambda_j X^j \in (A_i)$. As $\deg (U) < d_i$, $U$ is the zero polynomial and it follows that the $\lambda_i$ all have the value 0. Therefore $B$ is an independent set and so a basis of $\frac{\mathbf{F}_p[X]}{(A_i)}$. We have shown that $\frac{\mathbf{F}_p[X]}{(A_i)}$ has dimension $d_i$. It follows that the inertial degree $f_i$ is equal to $d_i$.

We now use Proposition 13.7:

$$n = [K : \mathbf{Q}] = \sum_{i=1}^{s} e_i' f_i \leq \sum_{i=1}^{s} e_i d_i.$$

As the degree of the polynomial $A_i^{e_i'}$ is $e_i d_i$, the product $A_1^{e_1'} \cdots A_s^{e_s'}$ has degree $\sum_{i=1}^{s} e_i d_i$. Given that this product is $h$, which has degree $n$, we have $\sum_{i=1}^{s} e_i d_i = n$.

To conclude we have

$$n = [K : \mathbf{Q}] = \sum_{i=1}^{s} e_i' f_i \leq \sum_{i=1}^{s} e_i d_i = n.$$

As $d_i = f_i$ and $e_i' \leq e_i$, we must have $e_i' = e_i$, as required.

To sum up, we have proved the following result, known as Dedekind’s factorization theorem:

**Theorem 17.2** Let $K = \mathbf{Q}(\alpha)$ be a number field, with $\alpha \in \mathcal{O}_K$, and $h = m(\alpha, \mathbf{Q})$. If $p$ is a prime number and $p \nmid [\mathcal{O}_K : \mathbf{Z}[\alpha]]$, then the factorization of $\mathcal{O}_K p$ into prime ideals has the same form as that of $h$ ($=-h$ modulo $p$) into irreducible polynomials.

**Remark** In proving Theorem 17.2, we have seen that $d_i = f_i$. If $Q_i$ is the ideal corresponding to $h_i$ and $Q_i$ lies over the prime $p$, then $\|Q_i\| = p^{d_i}$. This follows from the proof of Proposition 13.7.

Theorem 17.2 may be difficult to use in practice, since, in order to know that $p$ does not divide the index $[\mathcal{O}_K : \mathbf{Z}[\alpha]]$, we have to know this index. The corollary which follows provides us with a condition which is easier to check.

**Corollary 17.2** Let $K = \mathbf{Q}(\alpha)$ be a number field, with $\alpha \in \mathcal{O}_K$, and $h = m(\alpha, \mathbf{Q})$. If $p$ is a prime number and $p \nmid \text{disc}(\mathbf{Z}[\alpha])$, then the factorization of $\mathcal{O}_K p$ into prime ideals has the same form as that of $h$ ($=-h$ modulo $p$) into irreducible polynomials.

**Proof** As

$$\text{disc}(\mathbf{Z}[\alpha]) = [\mathcal{O}_K : \mathbf{Z}[\alpha]]^2 \text{disc}(\mathcal{O}_K),$$

if $p \nmid \text{disc}(\mathbf{Z}[\alpha])$, then $p \nmid [\mathcal{O}_K : \mathbf{Z}[\alpha]]$ and Theorem 17.2 applies. \qed

266
Examples 1. Let $K = \mathbb{Q}(\sqrt{d})$, where $d$ is a square-free integer. Then $O_K = \mathbb{Z}[\omega]$, where $\omega = \sqrt{d}$, if $d \equiv 2, 3 \pmod{4}$ and $\omega = \frac{1 + \sqrt{d}}{2}$, if $d \equiv 1 \pmod{4}$. In both cases $[O_K : \mathbb{Z}[\omega]] = 1$, so no prime number $p$ divides $[O_K : \mathbb{Z}[\omega]]$, hence Theorem 17.2 is applicable. In the first case $m(\omega, \mathbb{Q}) = -d + X^2$ and in the second case $m(\omega, \mathbb{Q}) = \frac{1-d}{4} - X + X^2$.

For instance, if $d = 2$ and $p = 3$, then

\[ m(\omega, \mathbb{Q}) = -2 + X^2 \equiv 1 + X^2 \pmod{3}, \]

which is irreducible. It follows that $O_K 3 = \mathbb{Q}$, for some prime ideal $\mathbb{Q}$.

To take another example, if $d = 5$ and $p = 3$, then we have

\[ m(\omega, \mathbb{Q}) = -1 - X + X^2 \equiv 4 + 4X + X^2 = (2 + X)^2 \pmod{5}. \]

Hence $O_K 5 = \mathbb{Q}^2$, for some prime ideal $\mathbb{Q}$, i.e., 5 is totally ramified in $O_K$.

2. Let $K = \mathbb{Q}(\sqrt[3]{10})$. An elementary calculation shows that $\text{disc}(\mathbb{Z}[\sqrt[3]{10}]) = -2700 = -2^2 \cdot 3^3 \cdot 5^3$.

From Corollary 17.2, for any prime number $p$ other than 2, 3 or 5, the form of the factorization of $O_K p$ can be determined from that of $m(\sqrt[3]{10}, \mathbb{Q}) \pmod{p}$.

For instance,

\[ m(\sqrt[3]{10}, \mathbb{Q}) = -10 + X^3 \equiv 4 + X^3 \pmod{7}, \]

which is irreducible, so $O_K 7 = \mathbb{Q}$, for some prime ideal $\mathbb{Q}$.

We now consider $O_K 3$. We look for an element $\beta \in O_K$ such that $K = \mathbb{Q}(\beta)$ and $3 \not| [O_K : \mathbb{Z}][\beta]$. (Of course, $\beta \neq \alpha$). If $\beta = \frac{1}{3}(1 + \sqrt[3]{10} + \sqrt[3]{100})$, then $\beta$ is a root of the polynomial $f(X) = -3 - 3X - X^2 + X^3$. As $f$ has no rational root, $f$ is irreducible over $\mathbb{Q}$ and so $f = m(\beta, \mathbb{Q})$. It is not difficult to see that $\mathbb{Q}(\beta) \subset K$, so we have

\[ [K : \mathbb{Q}] = [K : \mathbb{Q}(\beta)][\mathbb{Q}(\beta) : \mathbb{Q}] \implies [K : \mathbb{Q}(\beta)] = 1, \]

because $[K : \mathbb{Q}] = [\mathbb{Q}(\beta) : \mathbb{Q}] = 3$. Hence $K = \mathbb{Q}(\beta)$. As $\text{disc}(\mathbb{Z}[\beta]) = -300 = -2^2 \cdot 3 \cdot 5^2$, from the formula

\[ \text{disc}(\mathbb{Z}[\beta]) = [O_K : \mathbb{Z}][\beta]^2 \text{disc}(O_K), \]

we see that $3 \not| [O_K : \mathbb{Z}][\beta]$ and we may apply Theorem 17.2:

\[ m(\beta, \mathbb{Q}) = -3 - 3X - X^2 + X^3 \equiv (-1 + X)X^2 \pmod{3}, \]

so $O_K 3 = \mathbb{Q}_1 \mathbb{Q}_2$, for prime ideals $\mathbb{Q}_1, \mathbb{Q}_2$.

3. If $K = \mathbb{Q}(\zeta)$, where $\zeta$ is a primitive root of unity, i.e., $K$ is a cyclotomic extension of $\mathbb{Q}$, then $O_K = \mathbb{Z}[\zeta]$, so in this case $[O_K : \mathbb{Z}[\zeta]] = 1$ and no prime number $p$ divides $[O_K : \mathbb{Z}[\zeta]]$. We may apply Theorem 17.2 for any prime $p$. Let us consider the case where $\zeta = e^{\frac{2\pi i}{n}}$. Then

\[ m(\zeta, \mathbb{Q}) = \Phi_{p^n}(X) = \Phi_p(X^{p^{n-1}}), \]

where $\Phi_{p^n}$ is the cyclotomic polynomial of order $p^n$. Now,

\[ \Phi_p(X)(-1 + X) = -1 + X^p \equiv (-1 + X)^p \pmod{p}, \]

so

\[ \Phi_p(X) \equiv (-1 + X)^{p-1} \pmod{p} \implies \Phi_{p^n}(X) \equiv (-1 + X^{p^{n-1}})^{p-1} \pmod{p}, \]

and finally

\[ \Phi_{p^n}(X) \equiv (-1 + X)^{p^{n-1}(p-1)} \pmod{p}. \]
It follows that

$$O_{Kp} = Q_p^{n-1(p-1)},$$

for some prime ideal $Q$, i.e., $p$ is totally ramified in $O_K$.

Let us consider the case where $p = 5$ and $n = 1$. Then

$$\Phi_5(X) = 1 + X + X^2 + X^3 + X^4$$

and $O_5 5 = Q^4$, for some prime ideal $Q$. Now let us consider $O_{Kp}$, where $p \neq 5$. We have

$$\Phi_5(X) \equiv 1 + X + X^2 + X^3 + X^4 \pmod{3},$$

which is irreducible modulo 3. (To check this it is sufficient to observe that the polynomial has no root in $F_3$ and is not divisible by any irreducible polynomial of degree 2 in $F_3[X]$.) Thus $O_K 3 = Q$, where $Q$ is a prime ideal. A similar situation applies for $p = 7$.

On the other hand,

$$\Phi_5(X) \equiv (-3 + X)(-4 + X)(-5 + X)(-9 + X) \pmod{11},$$

so $O_K 11 = Q_1Q_2Q_3Q_4$, where the $Q_i$ are distinct prime ideals.

**Remark** We could have obtained the results in this example by applying the theory we developed in Section 13.9.
Chapter 18

Monogenic fields

A monogenic field is an algebraic number field $K$ for which there exists an element $\alpha$ in the ring of integers $O_K$ such that $O_K = \mathbb{Z}[\alpha]$. Such an element $\alpha$ is called a power generator. We have seen that quadratic fields and cyclotomic fields are monogenic. Also, from Proposition 17.1, if the discriminant of $\mathbb{Z}[\alpha]$ is square-free, then $K$ is monogenic. If $K$ is monogenic, then we may apply Dedekind’s factorization theorem to find the form of the factorization into prime ideals of the ideal $O_Kp$ for any prime $p$. If $K$ is monogenic and $O_K = \mathbb{Z}[\alpha]$, then $O_K$ has an integral basis, called a power basis, and the discriminant $\text{disc}(O_K)$ may be calculated using this basis, which is simpler than in the general case. In addition, such fields have other interesting properties as we will presently see.

Remark If the number field $K$ is monogenic and $\alpha$ is a power generator, then $\alpha$ is not unique. In fact, for any integer $n$, $\alpha + n$ is also a power generator. It is interesting to know whether there are other power generators. This may well be the case. The following result gives us an example.

Proposition 18.1 Let $\zeta$ be a primitive $p$th root of unity, with $p$ an odd prime, and $K = \mathbb{Q}(\zeta)$. If $\eta = 1 + \zeta^2 + \zeta^4 + \cdots + \zeta^{p-1}$ (even powers), then $\zeta$ and $\eta$ do not differ by an integer and $\mathbb{Z}[\zeta] = \mathbb{Z}[\eta]$.

Proof Let us suppose that there is an integer $k$ such that $\zeta - \eta = k$. We notice that $\eta = \frac{1}{1+\zeta}$, so

$$\frac{1}{1+\zeta} - \zeta = k \implies 1 = (k+\zeta)(1+\zeta) \implies 0 = (k-1) + (k+1)\zeta + \zeta^2.$$

However,

$$(k+1)^2 - 4(k-1) = 5 - 2k + k^2,$$

which is positive for all values of $k$. This implies that $\zeta$ is a real number, a contradiction. Hence $\zeta$ and $\eta$ do not differ by an integer.

Clearly, $\mathbb{Z}[\eta] \subset \mathbb{Z}[\zeta]$. To establish that $\mathbb{Z}[\zeta] \subset \mathbb{Z}[\eta]$, it is sufficient to show that $\zeta \in \mathbb{Z}[\eta]$. We have seen that $\eta$ is a unit with inverse $1 + \zeta$. As $\eta$ is invertible, from Proposition 11.3, the norm $N_{\mathbb{K}/\mathbb{Q}}(\eta)$ has the value $\pm 1$ and so the constant term of the minimal polynomial $f = m(\eta, \mathbb{Q})$ has the value $\pm 1$. Without loss of generality let us suppose that the constant term is positive. Then

$$f(X) = 1 + a_1X + a_2X^2 + \cdots + a_{s-1}X^{s-1} + X^s,$$

where the $a_i$ are integers. From this we obtain

$$1 = -a_1\eta - a_2\eta^2 - \cdots - a_{s-1}\eta^{s-1} - \eta^s \implies 1 + \zeta = -a_1 - a_2\eta - \cdots - a_{s-1}\eta^{s-2} - \eta^{s-1},$$

269
and it follows that $\zeta \in \mathbb{Z}[\eta]$. 

**Remark** It can be shown that a monogenic field can only have a finite number of distinct power generators, i.e., power generators which do not differ by an integer ([11]).

### 18.1 Monogenic and non-monogenic fields: examples

Other number fields than those we have already mentioned are monogenic; however, many number fields are not. Before giving examples of non-monogenic number fields, we will give some further examples of monogenic fields.

Suppose that $p$ is an odd prime and $\zeta$ a primitive $p$th root of unity in $\mathbb{C}$. Let $K = \mathbb{Q}(\zeta)$. We set $K_0 = \mathbb{Q}(\zeta + \zeta^{-1})$. We claim that $K_0$ is monogenic. First, $K_0$ is a real subfield of $K$ and $[K : Q] = [K : K_0][K_0 : Q]$. We set $f(x) = 1 - (\zeta + \zeta^{-1})x + x^2 \in K_0[x]$. Then $f(\zeta) = 0$ and $\zeta \notin K_0$, so $f = m(\zeta, K_0)$ and it follows that $[K : K_0] = 2$. From this we deduce that $[K_0 : Q] = \frac{p-1}{2}$ and that $K_0$ is a maximal subfield of $K$. Now we show that $K_0$ is monogenic, with $\zeta + \zeta^{-1}$ as power generator.

As $\zeta + \zeta^{-1}$ is the sum of two algebraic integers, it is an algebraic integer. Clearly, $\zeta + \zeta^{-1}$ belongs to $K_0$, thus $\mathbb{Z}[\zeta + \zeta^{-1}] \subset O_{K_0}$. The reverse inclusion requires more work.

Let $u \in O_{K_0}$. Then, by Proposition 11.10, we may write $u = \sum_{i=1}^{p-1} u_i \zeta^i$, with $u_i \in \mathbb{Z}$. Then

$$u = \sum_{i=1}^{p-1} u_i \zeta^i = \sum_{i=1}^{p-1} u_i \zeta^i + \sum_{i=1}^{p-1} u_i \zeta^{-i} = \sum_{i=1}^{p-1} u_i \zeta^i + \sum_{i=1}^{p-1} u_{p-i} \zeta^{p-i}.$$  

Because $u$ is real, we have $u = \bar{u}$, hence

$$u = \sum_{i=1}^{p-1} u_i \zeta^i = \sum_{i=1}^{p-1} u_i \zeta^{-i} = \sum_{i=1}^{p-1} u_i \zeta^{p-i}$$

Hence, for $i = 1, \ldots, \frac{p-1}{2}$, we have $u_i = u_{p-i}$ and so

$$u = \sum_{i=1}^{\frac{p-1}{2}} u_i (\zeta^i + \zeta^{-i}).$$

We claim that each of the elements $\zeta^i + \zeta^{-i}$ are linear sums of powers of $\zeta + \zeta^{-1}$. We use an induction on $i$. For $i = 1$ there is nothing to prove. Suppose that the result is true up to a given $i$ and consider the case $i + 1$. We have

$$(\zeta + \zeta^{-1})^{i+1} = \zeta^{i+1} + (i+1)\zeta^i + \zeta^i + \cdots + (i+1)\zeta^{i+1} + \zeta^{-(i+1)},$$

from which we deduce

$$(\zeta + \zeta^{-1})^{i+1} - (i+1)(\zeta^{i-1} + \zeta^{-(i+1)}) = \zeta^{i+1} + \zeta^{-(i+1)}.$$  

Using the induction hypothesis, we obtain that $\zeta^{i+1} + \zeta^{-(i+1)}$ is a linear sum of powers of $\zeta + \zeta^{-1}$. Thus we have proved the claim. It follows that $u$ belongs to $\mathbb{Z}[\zeta + \zeta^{-1}]$ and we have the inclusion
$O_K \subset \mathbb{Z}[\zeta + \zeta^{-1}]$, as required. Thus $\mathbb{Q}(\zeta + \zeta^{-1})$ is a monogenic field.

We now turn to cubic number fields. This case is more complex than that of quadratic number fields. We will first show that the field $\mathbb{Q}(\sqrt[3]{2})$ is monogenic. To prove this we need a preliminary result.

**Proposition 18.2** Let $K = \mathbb{Q}(\alpha)$, with $\alpha \in O_K$, be such that $[K : \mathbb{Q}] = n$ and $f = m(\alpha, \mathbb{Q})$. If $p$ is a prime number and $f$ is Eisenstein at $p$, then $p \not| [O_K : \mathbb{Z}[\alpha]]$.

**Proof** Let

$$f(X) = a_0 + a_1 X + \cdots + a_{n-1} X^{n-1} + X^n,$$

where $p | a_i$, for $i = 0, 1, \ldots, n-1$ and $p^2 \not| a_0$. We have

$$a_0 + a_1 \alpha + \cdots + a_{n-1} \alpha^{n-1} + \alpha^n = 0 \implies \mathbb{Z}[\alpha] = \mathbb{Z} + \mathbb{Z} \alpha + \cdots + \mathbb{Z} \alpha^{n-1}$$

and $a^n_0 \in \mathbb{Z}[\alpha]$. Also,

$$N_{K/\mathbb{Q}}(\alpha) = (-1)^n a_0 \not\equiv 0 \pmod{p^2}.$$

Suppose that $p | [O_K : \mathbb{Z}[\alpha]]$. Then there is an element of order $p$ in the quotient group $O_K/\mathbb{Z}[\alpha]$. This means that there exists $x \in O_K$, but not in $\mathbb{Z}[\alpha]$, such that $px \in \mathbb{Z}[\alpha]$. Thus

$$px = b_0 + b_1 \alpha + \cdots + b_{n-1} \alpha^{n-1},$$

with $b_i \in \mathbb{Z}$. As $x \not\in \mathbb{Z}[\alpha]$, there is at least one $b_i$ which is not divisible by $p$. Let $j$ be the smallest index with this property. So

$$y = x - \left( \frac{b_0}{p} + \frac{b_1}{p} \alpha + \cdots + \frac{b_{j-1}}{p} \alpha^{j-1} \right) = \frac{b_j}{p} \alpha^j + \frac{b_{j+1}}{p} \alpha^{j+1} + \cdots + \frac{b_{n-1}}{p} \alpha^{n-1}.$$

Because both $x$ and $\frac{b_0}{p} + \frac{b_1}{p} \alpha + \cdots + \frac{b_{j-1}}{p} \alpha^{j-1}$ belong to $O_K$, $y$ belongs to $O_K$ and so this is the case for $ya^{n-j-1}$. Now

$$ya^{n-j-1} = \frac{b_j}{p} \alpha^{n-1} + \frac{a^n}{p} (b_{j+1} + b_{j+2} \alpha + \cdots + b_{n-1} \alpha^{n-j-2}).$$

Since $a^n \in \mathbb{Z}[\alpha] \subset O_K$, we have $b_j \alpha^{n-1} \in O_K$. Also, the norm of an algebraic integer is an integer, hence

$$|N_{K/\mathbb{Q}}(\alpha)| = |N_{K/\mathbb{Q}}(\alpha^{n-1})| = \frac{b^n_j |N_{K/\mathbb{Q}}(\alpha)|}{p^n} = \frac{b^n_j |\alpha|}{p^n} \in \mathbb{Z}.$$

However,

$$p \not| b_j \quad \text{and} \quad p^2 \not| a_0,$$

so $|N_{K/\mathbb{Q}}(\alpha)| \not\in \mathbb{Z}$ and we have a contradiction. It follows that $p \not| [O_K : \mathbb{Z}[\alpha]]$. \hfill \square

We are now in a position to show that the field $K = \mathbb{Q}(\sqrt[3]{2})$ is monogenic. From Theorem 17.1 we have

$$\text{disc}(\mathbb{Z}[\sqrt[3]{2}]) = |O_K : \mathbb{Z}[\sqrt[3]{2}]|^2 \text{disc}(O_K).$$

The polynomial $m(\sqrt[3]{2}, \mathbb{Q})$ has the form $f(X) = -2 + X^3$ and its discriminant is $-108 = -2^2 \cdot 3^3$, so 2 and 3 are the only primes which could divide $|O_K : \mathbb{Z}[\sqrt[3]{2}]|$. As $f$ is Eisenstein at 2, by Proposition 18.2, 2 $\not| |O_K : \mathbb{Z}[\sqrt[3]{2}]|$. The number $1 + \sqrt[3]{2}$ is a root of the polynomial $g(X) = (-1 + X)^3 - 2 = -3 + 3X - 3X^2 + X^3$, which is Eisenstein at 3, so 3 $\not| |O_K : \mathbb{Z}[\sqrt[3]{2}]|$. However, $\mathbb{Z}[1 + \sqrt[3]{2}] = \mathbb{Z}[\sqrt[3]{2}]$, so 3 $\not| |O_K : \mathbb{Z}[\sqrt[3]{2}]|$. As both 2 and 3 do not divide $|O_K : \mathbb{Z}[\sqrt[3]{2}]|$, we must have $|O_K : \mathbb{Z}[\sqrt[3]{2}]| = 1$, i.e., $O_K = \mathbb{Z}[\sqrt[3]{2}]$ and $K$ is monogenic.
Exercise 18.1 Show that \( K = \mathbb{Q}(\sqrt[3]{5}) \) is monogenic.

Remark We may generalize these results in the following way. If \( q \) is a prime such that \( 3|(1+q) \) and \( 3^2 \not| (1+q) \), then the field \( \mathbb{Q}(\sqrt[3]{q}) \) is monogenic. For example, \( \mathbb{Q}(\sqrt[3]{11}) \) and \( \mathbb{Q}(\sqrt[3]{23}) \) are monogenic. In this way we obtain a family of monogenic cubic fields. We may be tempted to think that all cubic number fields are monogenic. The following example, due to Dedekind, shows that this is not the case.

Proposition 18.3 (Dedekind) If \( \theta \) is a root of the polynomial \( f(X) = -8 - 2X - X^2 + X^3 \), then \( K = \mathbb{Q}(\theta) \) is non-monogenic.

Proof First we calculate the discriminant of \( O_K \). As the polynomial \( f \) has no root in \( \mathbb{Q} \), \( f \) is irreducible over \( \mathbb{Q} \). Let \( \eta = \frac{\theta + \theta^2}{2} \). Then the set \( S = \{1, \theta, \eta\} \) is independant over \( \mathbb{Q} \). (If the set \( S \) is not independant, then \( \theta \) is the root of rational polynomial of degree 2 and it follows that \( f \) is reducible over \( \mathbb{Q} \).) Now \( A = \mathbb{Z} \oplus \mathbb{Z} \theta \oplus \mathbb{Z} \eta \) is a free \( \mathbb{Z} \)-module of rank 3 contained in \( O_K \), with basis \( S \). To calculate the discriminant of \( A \), we use the formula developped in Proposition 10.7, i.e., \( \text{disc}(A) = \det(X) \), where

\[
X = \begin{bmatrix}
T_{K/\mathbb{Q}(1)} & T_{K/\mathbb{Q}(\theta)} & T_{K/\mathbb{Q}(\eta)} \\
T_{K/\mathbb{Q}(\theta)} & T_{K/\mathbb{Q}(\theta^2)} & T_{K/\mathbb{Q}(\theta \eta)} \\
T_{K/\mathbb{Q}(\eta)} & T_{K/\mathbb{Q}(\eta \theta)} & T_{K/\mathbb{Q}(\eta^2)} \\
\end{bmatrix}.
\]

To determine the elements of this matrix we first find the respective matrices \( M_\theta \) and \( M_\eta \) of the applications \( x \mapsto \theta x \) and \( x \mapsto \eta x \) in the basis \( \mathcal{B} = \{1, \theta, \theta^2\} \):

\[
M_\theta = \begin{bmatrix} 0 & 0 & 8 \\ 1 & 0 & 2 \\ 0 & 1 & 1 \end{bmatrix}, \quad M_\eta = \begin{bmatrix} 0 & 4 & 8 \\ 1 & 1 & 6 \\ \frac{1}{2} & 1 & 2 \end{bmatrix}.
\]

Multiplying these matrices we find those of the applications \( x \mapsto \theta^2 x \), \( x \mapsto \theta \eta x \) and \( x \mapsto \eta^2 x \): \( M_{\theta^2} = M_\theta^2 \), \( M_{\theta \eta} = M_\theta M_\eta \) and \( M_{\eta^2} = M_\eta^2 \). We obtain

\[
M_{\theta^2} = \begin{bmatrix} 0 & 8 & 8 \\ 1 & 2 & 10 \\ 1 & 1 & 3 \end{bmatrix}, \quad M_{\theta \eta} = \begin{bmatrix} 4 & 8 & 16 \\ 1 & 6 & 12 \\ 1 & 2 & 8 \end{bmatrix}, \quad M_{\eta^2} = \begin{bmatrix} 6 & 12 & 40 \\ \frac{7}{2} & 9 & 22 \\ \frac{3}{2} & 5 & 14 \end{bmatrix}.
\]

Therefore

\[
X = \begin{bmatrix} 3 & 1 & 3 \\ 1 & 5 & 18 \\ 3 & 18 & 29 \end{bmatrix}.
\]

The determinant of \( X \) has the value \(-503\), so the discriminant of \( A \) is \(-503\). From Theorem 17.1 we have

\[
\text{disc}(A) = [O_K : A]^2 \text{disc}(O_K).
\]

As \( 503 \) is a prime number, we must have \( [O_K : A] = 1 \), i.e., the free groups \( O_K \) and \( A \) are the same. Thus any element \( \alpha \in O_K \) can be written \( \alpha = a + b \theta + c \eta \), with \( a, b, c \in \mathbb{Z} \). We aim to show that \( \text{disc}(\mathbb{Z}[\alpha]) \) is even and so \( O_K \neq \mathbb{Z}[\alpha] \). To begin with, we determine the matrix \( M_\alpha \) of the application \( x \mapsto \alpha x \) in the basis \( \mathcal{B} = \{1, \theta, \eta\} \):

\[
M_\alpha = \begin{bmatrix} a & 4c & 4b \\ b & a - b & 2c \\ c & 2b + 2c & a + 2b + 3c \end{bmatrix}.
\]

272
Reducing modulo 2, we obtain
\[
M_{\alpha} \equiv \begin{bmatrix} a & 0 & 0 \\ b & a-b & 0 \\ c & 0 & a+c \end{bmatrix} \pmod{2}.
\]

Then for the trace of the application \( x \mapsto \alpha x \) we have
\[
\text{tr } M_{\alpha}^k = \text{tr } (M_{\alpha}^k) \equiv a^k + (a-b)^k + (a+c)^k \equiv a + (a-b) + (a-c) \equiv a-b+c \pmod{2}.
\]

We now set
\[
Y = \begin{bmatrix} \text{tr}(1) & \text{tr}(\alpha) & \text{tr}(\alpha^2) \\ \text{tr}(\alpha) & \text{tr}(\alpha^2) & \text{tr}(\alpha^3) \\ \text{tr}(\alpha^2) & \text{tr}(\alpha^3) & \text{tr}(\alpha^4) \end{bmatrix}.
\]

From Proposition 10.7, we have \( \text{disc}(Z[\alpha]) = \det(Y) \). All the elements of \( Y \) are equivalent to \( a-b+c \pmod{2} \). If \( a-b+c \equiv 0 \pmod{2} \), then the last column of the matrix \( Y \) is composed of even numbers, hence \( \det(Y) \) is an even number. On the other hand, if \( a-b+c \equiv 1 \pmod{2} \), then all the elements of the matrix are odd. The determinant is composed of a sum of 3! products of 3 elements of the matrix, i.e., of a sum of 6 odd numbers, which is an even number. Therefore, in this case too, \( \det(Y) \) is an even number. We have shown that \( \text{disc}(Z[\alpha]) \) is an even number. As \( \text{disc}(O_K) \) is odd, we cannot have \( O_K = Z[\alpha] \), i.e., \( K \) is not monogenic.

Up to here we have only seen one example of a non-monogenic number field. We now turn to biquadratic number fields. (We recall that a number field is biquadratic if it is obtained by adjoining to \( Q \) the square roots of two square-free integers.) The family of such fields, which we will present, will provide us of infinite number of non-monogenic fields.

Let \( d \neq 1 \) be a square-free integer such that \( d \equiv 1 \pmod{3} \), then \( m(\sqrt{d}, Q) = -d + X^2 \). Let us write \( f \) for this minimal polynomial. Reducing modulo 3 we obtain \( f(X) = (1 + X)(-1 + X) \), so from Dedekind’s factorization theorem we obtain \( O_{Q(\sqrt{d})} 3 = P_1P_2 \), where \( P_1, P_2 \) are prime ideals in \( O_{Q(\sqrt{d})} \), i.e., 3 splits completely in \( O_{Q(\sqrt{d})} \).

Now let \( d_1, d_2 \) be distinct square-free integers such that \( d_i \neq 1 \) and \( d_i \equiv 1 \pmod{3} \), for \( i = 1, 2 \). From Theorem 13.12, the prime 3 splits completely in \( O_K \), where \( K = Q(\sqrt{d_1}, \sqrt{d_2}) \), i.e.,
\[
O_K 3 = P_1P_2P_3P_4,
\]

where the \( P_i \) are prime ideals in \( O_K \). Suppose that there exists \( \alpha \in O_K \) such that \( O_K = Z[\alpha] \); then \( 3 \mid [O_K : Z[\alpha]] \). If we set \( f = m(\alpha, Q) \), then from Dedekind’s factorization theorem we obtain
\[
\bar{f}(X) = (-a_1 + X)(-a_2 + X)(-a_3 + X)(-a_4 + X),
\]

where \( \bar{f} \) denotes the reduction of \( f \) modulo 3 and \( a_1, a_2, a_3, a_4 \in F_3 \). However, \( F_3 \) contains only 3 distinct elements, a contradiction. It follows that \( O_K \neq Z[\alpha] \) and so \( K \) is not monogenic.

**Example** The number field \( Q(\sqrt{7}, \sqrt{10}) \) is not monogenic.

More on biquadratic number fields can be found, for example, in the articles [9], [16]).

**Remark** Proposition 18.2 together with Theorem 17.2 may be used to prove the following result:
Proposition 18.4 If \( K = \mathbb{Q}(\alpha) \) and the polynomial minimal \( h \) is Eisenstein at \( p \), then \( \bar{h} = X^n \), so the factorization of \( O_Kp \) into prime ideals has the form \( O_K = P^n \), i.e., \( p \) is totally ramified in \( O_K \).

PROOF We leave the proof as an exercise.

18.2 Properties of orders in a number ring

We recall that an order in a number ring \( K \) is a subring \( R \) of \( O_K \) whose index as a subgroup of \( O_K \) is finite. We know that \( O_K \) is a Dedekind domain, but what can we say of an order \( R \) which is a proper subring of \( O_K \)? It turns out that certain properties of \( O_K \) carry over to \( R \), but not all. (Of course, we are primarily interested in orders of the form \( \mathbb{Z}[\alpha] \), where \( \mathbb{Z}[\alpha] \) is a proper subset of \( O_K \).)

Proposition 18.5 If \( R \) is an order, then \( R \) is noetherian.

PROOF It is sufficient to show that every ideal in \( R \) is finitely generated. If \( I \) is the zero ideal, then there is nothing to prove, so let us suppose that this is not the case. Let \( I \) be a nonzero ideal. As \( I \) is a subgroup of \( O_K \), \( I \) is a free group of rank at most that of \( O_K \). Hence \( I \) has a finite basis, which implies that it is finitely generated. \( \square \)

We now consider the fraction field of \( R \). But first a preliminary result (not without interest).

For an order \( R \), we write \( \mathbb{Q}R \) for the collection of sums of the form \( \sum_{i=1}^{k} q_i r_i \), with \( q_i \in \mathbb{Q} \) and \( r_i \in R \).

Lemma 18.1 Let \( K \) be a number field with ring of integers \( O_K \). If \( R \) is an order in \( K \), then \( \mathbb{Q}O_K = \mathbb{Q}R = K \).

PROOF First we show that \( \mathbb{Q}O_K = K \). Clearly \( \mathbb{Q}O_K \subset K \). Suppose now that \( \alpha \in K \). As \( \alpha \) is algebraic over \( \mathbb{Q} \), from Lemma 11.2 there exists a positive integer \( k \) such that \( k\alpha \in O_K \). Hence \( \alpha \in \mathbb{Q}O_K \) and so \( K \subset \mathbb{Q}O_K \). As \( \mathbb{Q}O_K \subset K \), we have an equality.

Now suppose that \( R \) is any order in \( O_K \). As \( R \subset O_K \), we have \( \mathbb{Q}R \subset \mathbb{Q}O_K = K \). We now consider the reverse inclusion. There exists a basis \( \{e_1, \ldots, e_n\} \) of \( O_K \) and positive integers \( d_1, \ldots, d_n \) such that \( \{d_1 e_1, \ldots, d_n e_n\} \) is a basis of \( R \). Let \( \alpha \in K \). From Lemma 11.2 there exists a positive integer \( k \) such that \( k\alpha \in O_K \). Therefore we can find integers \( k_1, \ldots, k_n \) such that

\[
k\alpha = \sum_{i=1}^{n} k_i e_i = \sum_{i=1}^{n} d_i k_i e_i \in \mathbb{Q}R \implies \alpha \in \mathbb{Q}R.
\]

Therefore \( K \subset \mathbb{Q}R \) and it follows that \( K = \mathbb{Q}R \). \( \square \)

We recall that the fraction field of \( O_K \) is \( K \). It turns out that this is also the case for any order in \( O_K \).

Proposition 18.6 Let \( R \subset O_K \) be an order. Then the fraction field of \( R \) is \( K \).

PROOF Let us write \( \text{Frac}(R) \) for the fraction field of \( R \). If \( \alpha \in K \), then, from Lemma 18.1, there exist \( q_1, \ldots, q_k \in \mathbb{Q} \) and \( r_1, \ldots, r_k \in R \) such that \( \alpha = \sum_{i=1}^{k} q_i r_i \). We may write \( q_i = \frac{a_i}{b_i} \), with \( a_i, b_i \in \mathbb{Z} \) and \( b_i \neq 0 \). Then

\[
\alpha = \sum_{i=1}^{k} \frac{a_i}{b_i} r_i = \sum_{i=1}^{k} \frac{a_i r_i}{b_i} \in \text{Frac}(R),
\]

274
because both \( a_i r_i \) and \( b_i \) belong to \( R \). Thus \( K \subset \text{Frac}(R) \). By definition \( \text{Frac}(R) \subset K \), hence the equality \( \text{Frac}(R) = K \).

As \( O_K \) is a Dedekind domain, every nonzero prime ideal in \( O_K \) is maximal. This is also the case for orders.

**Proposition 18.7** If \( R \subset O_K \) is an order, then every nonzero prime ideal is maximal.

**Proof** Let \( P \) be a nonzero prime ideal in \( R \) and \( a \) a nonzero element of \( P \). Let \( f = m(a, Q) \). Then \( f(X) = \sum_{i=0}^{n-1} c_i X^i + X^m \in \mathbb{Z}[X] \). As \( f \) is minimal, \( c_0 \neq 0 \). Given that \( f(a) = 0 \), we have

\[-c_0 = c_1 a + \cdots + c_{n-1} a^{n-1} + a^n \implies c_0 \in P.\]

The quotient \( R/P \) is a finitely generated \( \mathbb{Z} \)-module, such that \( c_0(R/P) = 0 \) (\( c_0 \in P \)). From the theorem of the decomposition of finitely generated modules over a P.I.D., we know that \( R/P \) is a direct sum of cyclic submodules [5]. As \( c_0(R/P) = 0 \), all these submodules must be finite and so \( R/P \) is finite. However, \( R/P \) is an integral domain and a finite integral domain is a field. It follows that \( P \) is a maximal ideal.

**Exercise 18.2** In the proof of the above proposition we have used the fact that a finite integral domain is a field. Prove this statement.

Up to here the properties of rings of integers have carried over to orders. However, one important property does not carry over and this prevents orders which are not rings of integers from being Dedekind domains. We recall that an integral domain \( R \) is normal if its integral closure in its field of fractions is \( R \) itself. This is so for rings of integers (Proposition 11.7), but is not true for other orders.

**Theorem 18.1** Let \( K \) be a number field, with ring of integers \( O_K \). If \( R \) is an order in \( K \) and \( R \neq O_K \), then \( R \) is not a normal domain.

**Proof** Since \( R \neq O_K \), there exists \( \beta \in O_K \setminus R \). As \( O_K \subset \text{Frac}(O_K) = \text{Frac}(R) \), \( \beta \) lies in \( \text{Frac}(R) \). Moreover, \( \beta \) is an algebraic integer, there exists a monic polynomial \( f \in \mathbb{Z}[X] \subset R[X] \) such that \( f(\beta) = 0 \). Hence \( \beta \) lies in the integral closure of \( R \). However, \( \beta \notin R \), so the integral closure of \( R \) in its field of fractions is not \( R \), i.e., \( R \) is not normal.

**Corollary 18.1** An order \( R \) in a number field \( K \) is a Dedekind domain if and only if \( R = O_K \).

An important property of Dedekind domains is the expression of a nonzero fractional ideal as a unique product of powers of prime ideals, with positive powers for integral ideals. This property does not carry over to orders which are proper subrings of number rings.

**Proposition 18.8** Let \( K \) be a number field with ring of integers \( O_K \). If the order \( R \) is a proper subset of \( O_K \), then the unique factorization of fractional ideals fails.

**Proof** Suppose that \( R \) has the factorization property. We will show that this implies that every prime ideal is invertible. Let \( P \) be a prime ideal of \( R \) and \( a \) a nonzero element of \( P \). By hypothesis

\[(a) = Q_1 \cdots Q_s,\]

where the \( Q_i \) are prime ideals in \( R \). Then

\[R = Q_1(\frac{1}{a}Q_2 \cdots Q_s),\]

275
so $Q_1$ is invertible. In the same way, the ideals $Q_2, \ldots, Q_s$ are also invertible. If no $Q_i$ is contained in $P$, then for each $i$ there is an element $c_i \in Q_i$ which does not belong to $P$. However, the product $c_1 \cdots c_s \in P$, which is impossible because $P$ is a prime ideal. Therefore, for some $i$, we have $Q_i \subset P$. As every nonzero prime ideal is maximal, we must have $Q_i = P$ and so $P$ is invertible.

We now consider a nonzero fractional ideal $I$. By hypothesis we can write $I = P^{a_1} \cdots P^{a_n}$, where $a_1, \ldots, a_n \in \mathbb{Z}$. Then $I$ is invertible, with $I^{-1} = P^{-a_n} \cdots P^{-a_1}$.

Thus every nonzero fractional ideal is invertible.

In the proof of Proposition 12.9 we showed that, if $R$ is an integral domain such that every nonzero fractional ideal is invertible, then $R$ is integrally closed in its fraction field, i.e., $R$ is normal. From Theorem 18.1 we see that $R = \mathcal{O}_K$, a contradiction. Therefore the factorization property does not apply to orders which are not maximal.

276

18.3 Different of a number ring

We now return to the different, which we defined in Chapter 15 for a general Dedekind domain. We will be particularly interested in number rings and will first summarize the discussion of the different in this context.

The ring of integers $\mathbb{Z}$ is a Dedekind domain and $\mathbb{Q}$ is its field of fractions. (In the language of Chapter 15, $\mathbb{Z} = C$ and $\mathbb{Q} = K$.) Let $L$ be a number field and $\mathcal{O}_L$ its ring of integers. $\mathcal{O}_L$ is the integral closure of $\mathbb{Z}$ in $L$. (In the language of Chapter 15, $\mathcal{O}_L = D$.) We set

$$\mathcal{O}_L^* = \{x \in L : T_L/\mathbb{Q}(xy) \in \mathbb{Z}, \forall y \in \mathcal{O}_L\}.$$ 

From Proposition 15.3, $\mathcal{O}_L^*$ is a fractional ideal of $\mathcal{O}_L$. We now set $\Delta(\mathcal{O}_L|\mathbb{Z}) = \mathcal{O}_L^*-1$. (To simplify the notation we will write $\Delta$ for $\Delta(\mathcal{O}_L|\mathbb{Z})$. $\Delta$ is called the different of $\mathcal{O}_L$ over $\mathbb{Z}$, or simply the different of $\mathcal{O}_L$. From Proposition 15.4 we know that $\Delta$ is an integral ideal of $\mathcal{O}_L$.

The bilinear form defined on $L \times L$ by $(x, y) \mapsto T_L/\mathbb{Q}(xy)$ is nondegenerate. If $\mathcal{B} = \{x_1, \ldots, x_n\}$ is an integral basis of $\mathcal{O}_L$, then $\mathcal{B}$ is a basis of $L$ over $\mathbb{Q}$. There is a basis $\mathcal{B}^* = \{x_1^*, \ldots, x_n^*\}$ of $L$ over $\mathcal{O}_L$ such that $T_L/\mathbb{Q}(x_ix_j^*) = \delta_{ij}$, where $\delta_{ij}$ is the Kronecker symbol. This second basis is called the dual basis of $\mathcal{B}$ and, from Proposition 15.2, is a basis of the free $\mathbb{Z}$-module $\mathcal{O}_L^*$.

Different and discriminant

In this subsection our principal aim is to prove a relation between the discriminant and the different of a number ring $\mathcal{O}_L$.

**Theorem 18.2** For a number ring $\mathcal{O}_L$ we have

$$\|\Delta(\mathcal{O}_L|\mathbb{Z})\| = |\text{disc}(\mathcal{O}_L)|.$$
As $O_L^*$ is a fractional ideal of $O_L$, there exists a nonzero element of $\alpha$ in $O_L$ such that $\alpha O_L^*$ is an ideal of $O_L$. We claim that we may choose $\alpha \in N^*$. As $L$ is a finite extension of $\mathbb{Q}$, each $x_i^*$ is algebraic over $\mathbb{Q}$. From Lemma 11.2, there is a positive integer $\alpha_i$ such that $\alpha_i x_i^*$ is an algebraic integer and so belongs to $O_L$. If $\alpha = \alpha_1 \cdots \alpha_n$, then $\alpha x_i^* \in O_L$, for all $i$, and it follows that $\alpha O_L^* \subset O_L$.

Now $\alpha O_L^* = \mathbb{Z} \alpha x_1^* + \cdots + \mathbb{Z} \alpha x_n^*$.

Given that $\alpha x_i^* \in O_L$, we may write

$$\alpha x_i^* = \sum_{j=1}^{n} a_{ij} x_j \quad \Rightarrow \quad x_i^* = \sum_{j=1}^{n} \frac{a_{ij}}{\alpha} x_j,$$

where the $a_{ij}$ are rational numbers. Also, for $i = 1, \ldots, n$, we have

$$x_i = \sum_{j=1}^{n} b_{ij} x_j,$$

with the $b_{ij}$ rational numbers. Let us set $A = (a_{ij})$, $A' = (\frac{a_{ij}}{\alpha})$ and $B = (b_{ij})$. These matrices have their components in $\mathbb{Q}$ and $A' B^t = I_n$, i.e., $B^t = A^{-1}$. Then

$$T_{L/\mathbb{Q}}(x_i x_j) = T_{L/\mathbb{Q}} \left( \sum_{k=1}^{n} b_{ik} x_k^* x_j \right) = \sum_{k=1}^{n} b_{ik} T_{L/\mathbb{Q}}(x_k^* x_j) = b_{ij}.$$

Therefore, by Proposition 10.7,

$$\det(B) = \text{disc}(O_L). \quad (18.1)$$

Now $\alpha O_L^*$ is an ideal in $O_L$ and has the integral basis $B' = \{\alpha x_1^*, \ldots, \alpha x_n^*\}$. Using Theorem 13.3 we obtain

$$\text{disc}_{L/\mathbb{Q}}(\alpha x_1^*, \ldots, \alpha x_n^*) = \|\alpha O_L^*\|^2 \text{disc}(O_L).$$

However, from Proposition 10.6 we also have

$$\text{disc}_{L/\mathbb{Q}}(\alpha x_1^*, \ldots, \alpha x_n^*) = \det(A)^2 \text{disc}(O_L),$$

which shows that

$$|\det(A)| = \|\alpha O_L^*\| \quad \Rightarrow \quad |\det(A)| = \frac{\|\alpha O_L^*\|}{\alpha^n}.$$  

Moreover,

$$\|\alpha O_L^*\||O_L^{-1}^*\| = \|\alpha O_L O_L^{-1}\| = \|((\alpha))\| = \alpha^n \quad \Rightarrow \quad ||O_L^{-1}|| = \frac{\alpha^n}{\|\alpha O_L^*\|}.$$

Since $A'$ is the inverse of $B^t$, we have

$$||O_L^{-1}|| = |\det(B)| = |\text{disc}(O_L)|,$$

where we have used the relation (18.1).

**Corollary 18.2** If the discriminant of $O_L$ is a prime, then $\Delta$ is a prime ideal.
PROOF If disc$(O_L)$ is equal to a prime number, then so is $||\Delta(O_L[Z])||$. From Proposition 13.5, $\Delta$ is a prime ideal. \hfill $\Box$

**Factorizing the different**

The different is an ideal and so has a factorization into prime ideals. Here we will be concerned with this factorization. We will first study some examples where the number field is monogenic before giving a more general result.

Some examples in the monogenic case

The goal of this paragraph is to provide the decomposition into prime ideals of the different of the number rings of the cyclotomic fields $Q(\zeta_p)$ and the quadratic field $Q(\sqrt{10})$, using the tools which we have previously developed. In particular, we will reconsider Corollary 15.4. We may interpret this result in the context of number fields. Let $L$ be a number field which is a normal extension of $Q$. If $L$ is monogenic, $\alpha$ a power generator and $f = \min(\alpha, Q)$, then $\Delta(O_L[Z]) = O_L(f'(\alpha))$.

We start with cyclotomic fields. Let $\zeta_p$ be a primitive $p$th root of unity and $L = Q(\zeta_p)$. We know that $L$ is monogenic and that the minimal polynomial $m(\zeta_p, Q)$ has the form $f(X) = \frac{1 + X}{1 + \frac{X}{p}} = 1 + X + \cdots + X^{p-1}$. Then

$$f'(X) = \frac{pX^{p-1}(-1 + X) - (-1 + X^p)}{(-1 + X)^2} \implies f'(\zeta_p) = \frac{p\zeta_p^{p-1}}{1 + \zeta_p}.$$ 

Since $\zeta_p^{p-1}$ is a unit, we find

$$\Delta = O_L \frac{p}{1 + \zeta_p}.$$ 

Moreover, in the proof of Proposition 11.10 (equation (11.2)) we saw that $O_{Q(\zeta_p)}^p = O_{Q(\zeta_p)}(1 - \zeta_p)^p$, therefore

$$\Delta = O_L(1 - \zeta_p)^{p-2}.$$ (18.2)

From Section 13.9, $O_L(1 - \zeta_p)$ is a prime ideal, so the expression (18.2) is the decomposition of $\Delta$ into prime ideals.

Now let us look at quadratic number fields. If $L = Q(\sqrt{d})$, with $d \equiv 2, 3 \pmod{4}$, then $O_L = Z[\sqrt{d}]$ and the minimal polynomial $m(\sqrt{d}, Q)$ has the form $f(X) = -d + X^2$. It follows that $\Delta = O_L(2\sqrt{d})$. On the other hand, if $d \equiv 1 \pmod{4}$, then $L = Q(\frac{1+\sqrt{d}}{2})$ and $O_L = Z[\frac{1+\sqrt{d}}{2}]$. In this case the minimal polynomial $m(\frac{1+\sqrt{d}}{2}, Q)$ has the form $f(X) = \frac{1-d}{2} - X + X^2$ and so $f'(X) = -1 + 2X$. Therefore $\Delta = O_L\sqrt{d}$.

Finding the factorization of the different may not be so easy as in the case of the cyclotomic field above. From Corollary 15.3 a nonzero prime ideal $Q$ in $O_L$ divides the different $\Delta$ if and only if $Q$ lies over a prime which ramifies in $O_L$. Thus we can find the factors in the decomposition, but not necessarily their powers. Let us consider an example. Let $L = Q(\sqrt{10})$. Then $\Delta = O_L(2\sqrt{10})$. The discriminant of $O_L$ has the value $40 = 2^35$, so the primes which ramify in $O_L$ are 2 and 5. As $O_L = Z[\sqrt{10}]$, from Theorem 17.2, there exist prime ideals $Q_2$ and $Q_5$ in $Z[\sqrt{10}]$ such that

$$Z[\sqrt{10}]2 = Q_2^2 \quad \text{and} \quad Z[\sqrt{10}]5 = Q_5^2.$$

278
Therefore $Q_2$ and $Q_5$ are the prime divisors of $\Delta$ and $e_{Q_2} = e_{Q_5} = 2$. In fact,

$Q_2 = (2, \sqrt{10}) \quad \text{and} \quad Q_5 = (5, \sqrt{10})$.

To see this, we notice that

$$\frac{\mathbb{Z}[(\sqrt{10})]}{(2, \sqrt{10})} \simeq \mathbb{Z}_2 \quad \text{and} \quad \frac{\mathbb{Z}[(\sqrt{10})]}{(5, \sqrt{10})} \simeq \mathbb{Z}_5,$$

hence $(2, \sqrt{10})$ and $(5, \sqrt{10})$ are maximal ideals, and therefore prime ideals. There is a unique prime ideal in $\mathbb{Z}[(\sqrt{10})]$ dividing $\mathbb{Z}[(\sqrt{10})]2$ and $(2, \sqrt{10})$ is such an ideal. Therefore $Q_2 = (2, \sqrt{10})$.

In the same way $Q_5 = (5, \sqrt{10})$. In addition, the characteristics of $\frac{\mathbb{Z}[(\sqrt{10})]}{Q_2}$ and $\frac{\mathbb{Z}[(\sqrt{10})]}{Q_5}$ are respectively 2 and 5. From Theorem 15.5, as the characteristic of $\frac{\mathbb{Z}[(\sqrt{10})]}{Q_5}$ (5) does not divide $e_{Q_5}(= 2)$, we have $s_{Q_5} = e_{Q_5} - 1 = 2 - 1 = 1$. On the other hand, the characteristic of $\frac{\mathbb{Z}[(\sqrt{10})]}{Q_2}$ (2) divides $e_{Q_2}(= 2)$ and so from Theorem 15.5 we can only deduce that $s_{Q_2} \geq e_{Q_2} - 1 = 2 - 1 = 1$, which of course we already know.

To determine $s_{Q_2}$ we turn to Theorem 15.6. We recall the definition of the ramification groups in the context of number rings. We suppose that $L$ is a finite normal extension of $\mathbb{Q}$, $p$ a prime in $\mathbb{Z}$ and $Q \subset O_L$ a prime ideal lying over $p$. We set $G = Gal(L/\mathbb{Q})$. Then, for $i \in \mathbb{N}$, we define the ramification groups $V_i$ by

$$V_i = \{ \sigma \in G : \sigma(\alpha) \equiv \alpha \mod Q^{i+1} \forall \alpha \in O_L \}.$$

The particular case $V_0$ is called the inertia group. The $V_i$ form a descending sequence and from Corollary 13.9 there is an index $r$ such that $V_r = \{ id \}$. From Theorem 15.6, if $p$ is totally ramified in $O_L$ and $Q$ is the unique prime ideal in $O_L$ lying over $p$, then

$$s_Q = \sum_{i=1}^{r-1} (|V_i| - 1).$$

Thus, in order to determine the value of $s_{Q_2}$ we need to find the corresponding ramification groups $V_i$, i.e., the $V_i$ with $G = Gal(\mathbb{Q}(\sqrt{10})/\mathbb{Q})$ and $Q = Q_2 = (2, \sqrt{10})$. The Galois group $G$ has two elements, namely the identity and the automorphism $\sigma$ for which $\sigma(\sqrt{10}) = -\sqrt{10}$. Hence $V_i$ is equal to the Galois group or contains only the identity. The former will be the case if and only if $-\sqrt{10} \equiv \sqrt{10} \mod Q_2^{i+1}$, i.e., when $2\sqrt{10} \in Q_2^{i+1}$. This is the case for $i = 0, 1, 2$, but not for $i = 3$, because

$$(2, \sqrt{10})^4 = (\mathbb{Z}[(\sqrt{10})]/2)^4 = \mathbb{Z}[(\sqrt{10})]/4.$$

Therefore,

$$|V_0| = |V_1| = |V_2| = 2, \quad |V_3| = 1 \implies s_{Q_2} = (2 - 1) + (2 - 1) + (2 - 1) = 3.$$

To conclude

$$\Delta(O_{\mathbb{Q}(\sqrt{10})}/\mathbb{Z}) = (2, \sqrt{10})^3(5, \sqrt{10}).$$

The non-monogenic case

If $L$ is a monogenic field, then there exists an algebraic number $\alpha \in O_L$ such that $L = \mathbb{Q}(\alpha)$ and $O_L = \mathbb{Z}[\alpha]$. We have seen that in this case $\Delta(O_L/\mathbb{Z}) = O_L f'(\alpha)$, where $f = m(\alpha, \mathbb{Q})$. From Proposition 10.1, $f$ is the characteristic polynomial of $\alpha$, so we may say that $\Delta$ divides the principal ideal generated by the derivative of the characteristic polynomial of $\alpha$ evaluated at $\alpha$. We may generalise this to the case of a field which is not monogenic.

279
Proposition 18.9 Let $L$ be a number field which is a normal extension of $\mathbb{Q}$ and not monogenic and $\alpha \in O_L$. If $g$ is the characteristic polynomial of $\alpha$, then $\Delta(O_L|\mathbb{Z})$ divides $O_L g'(\alpha)$.

Proof If $L \neq \mathbb{Q}(\alpha)$, then $[L : \mathbb{Q}(\alpha)] = r > 1$. From Proposition 10.1, $g = f^r$, where $f = m(\alpha, \mathbb{Q})$. It follows that $g'(\alpha) = 0$ and so $\Delta|O_L g'(\alpha)$.

Now suppose that $L = \mathbb{Q}(\alpha)$. Using Proposition 15.8 we have

$$Z[\alpha] \subset O_L \implies O_L^* \subset Z[\alpha]^* \implies \Delta^{-1} \subset \frac{1}{f'(\alpha)} Z[\alpha] \subset \frac{1}{f'(\alpha)} O_L.$$ 

Taking inverses we obtain

$$O_L f'(\alpha) \subset \Delta \implies \Delta|O_L f'(\alpha).$$

From Proposition 15.8, $g = f$ and hence the result. \hfill \Box
Chapter 19

Elementary class groups

The determination of class groups is not easy. In this chapter we identify class groups of some number fields in each case using a particular set of generators. We will certainly not be exhaustive. In Chapter 14, for a number field $K$ of degree $n$ over $\mathbb{Q}$, we defined the Minkowski bound

$$\lambda = \frac{n!}{n^n} \left( \frac{4}{\pi} \right)^s \sqrt{\text{disc}(O_K)},$$

where $2s$ is the number of complex embeddings of $K$ into $\mathbb{C}$. We observed that if $\lambda$ is less than 2, then the class number must be 1, because every class contains a nonzero ideal $J$ whose norm is less than $\lambda$. This is a sufficient condition, but is not necessary as we will presently show.

Let us look more closely into the structure of the class group. Each class contains a nonzero ideal $J$ whose norm is bounded by $\lambda$. If $P$ is a prime ideal in the decomposition of $J$, then, by Proposition 13.6, $P$ contains a unique prime number $p$ and $\|P\| = p^m$, for some $m \in \mathbb{N}^*$; clearly $p \leq \lambda$. Therefore the class group is generated by the classes of prime ideals $P$ in $O_K$ containing a prime $p \leq \lambda$. Certain of these classes may contain a principal ideal, in which case they are equal to the identity $e$, the class composed of principal ideals and we may eliminate them. Finally, we are left with the identity $e$ alone, in which case the group is trivial, or a set of generators distinct from $e$ and we look for relations between them. To understand the procedure we will look at some examples.

Example 1. $K = \mathbb{Q}(\sqrt{14})$

First we calculate the Minkowski bound:

$$\lambda = \frac{2!}{2^2} \sqrt{4 \cdot 14} = \sqrt{14} \quad \text{and} \quad 3 < \sqrt{14} < 4,$$

so we look for prime ideals $P$ containing 2 or 3.

There is a unique prime ideal $P$ containing 3. Indeed, 3 belongs to $P$ implies that $P$ contains $O_K3$. We set $f = m(\sqrt{14}, \mathbb{Q})$. Then $f(X) = -14 + X^2$ and the reduction modulo 3 of $f$ is $f_2(X) = 1 + X^2$, which is irreducible. Then Theorem 17.2 ensures that $O_K3$ is a prime ideal and so $P = O_K3$. Thus there is a unique prime ideal containing 3, which we will note $P_3$. $P_3$ is clearly principal.

Now we consider prime ideals containing 2. In fact, there is only one such ideal $P$. Indeed, 2 belongs to $P$ implies that $P$ contains $O_K2$. By Proposition 18.4 there exists a prime ideal
Let $P_2$ in $O_K$ such that $O_K2 = P_2^2$. Hence $P = P_2$. We claim that $P_2$ is principal. Since $2 = (4 + \sqrt{14})(4 - \sqrt{14})$, we may write
\[
P_2^2 = O_K2 = O_K(4 + \sqrt{14})O_K(4 - \sqrt{14}) \implies P_2 = O_K(4 + \sqrt{14}) = O_K(4 - \sqrt{14}),
\]
using the unique decomposition of ideals. Hence $P_2$ is principal.

As $P_2$ and $P_3$ are principal, the class number is 1, i.e., the class group is reduced to the identity. This example shows that the Minkowski bound may be greater than 2 and at the same time the class number 1.

**Example 2. $K = \mathbb{Q}(\sqrt{-5})$**

We calculate the Minkowski bound:
\[
\lambda = \frac{2!}{2^2} \left(\frac{4}{\pi}\right)^1 \sqrt{4 \cdot 5} = \frac{2}{\pi} \sqrt{20} = \frac{4}{\pi} \sqrt{5} \quad \text{and} \quad 2 < \frac{4}{\pi} \sqrt{5} < 3.
\]
The only prime we need to consider is 2. We set $f = m(\sqrt{-5}, \mathbb{Q})$. Then $f(X) = 5 + X^2$. The reduction modulo 2 of $f$ is $f_2(X) = 1 + X^2 = (1 + X)^2$, so there is a prime ideal $P_2$ in $O_K$ such that $O_K2 = P_2^2$. Thus there is a unique prime ideal lying over 2. This implies that the class group is cyclic. We now determine its order, which must be 1 (if $P_2$ is principal) or 2.

We claim that $P_2$ is not principal. If $P_2$ is principal, then we can write
\[
P_2 = O_K(a + b\sqrt{-5}) \implies P_2^2 = O_K(a + b\sqrt{-5})^2 \implies 2 = (a + b\sqrt{-5})^2 u,
\]
where $u$ is a unit in $O_K$. Taking norms we obtain
\[
N_{K/\mathbb{Q}}(2) = N_{K/\mathbb{Q}}((a + b\sqrt{-5})^2) = N_{K/\mathbb{Q}}(a) \implies 4 = \pm(a^2 + 5b^2)^2,
\]
which is impossible with $a, b \in \mathbb{Z}$. Hence $P_2$ is not principal and we have two distinct classes, i.e., the class group is cyclic of order 2.

If the class number is prime, then we know that the class group is cyclic. On the other hand, if the class number is greater than 1 and not prime, then we need to find the distinct classes and study the relation between them.

**Example 3. $K = \mathbb{Q}(\sqrt{-14})$**

We calculate the Minkowski bound:
\[
\lambda = \frac{2!}{2^2} \left(\frac{4}{\pi}\right)^1 \sqrt{4 \cdot 14} = \frac{4}{\pi} \sqrt{14} \quad \text{and} \quad 4 < \frac{4}{\pi} \sqrt{14} < 5.
\]
We need to consider the primes less than 5, namely 2 and 3.

There is a unique prime ideal $P$ containing 2. Let $f = m(\sqrt{-14}, \mathbb{Q})$. Then $f(X) = 14 + X^2$. The polynomial $f$ is Eisenstein at 2, so there is a prime ideal $P_2$ such that $O_K2 = P_2^2$ and it follows that $P = P_2$.

The situation is different for 2. In fact, there are two prime ideals containing 3. The reduction of $f$ modulo 3 is $f_3(X) = -1 + X^2 = (-1 + X)(1 + X)$, therefore there are prime ideals $P_3$ and $P_3'$ such that $O_K3 = P_3P_3'$. Thus the class group is generated by the classes $[P_2], [P_3]$ and $[P_3']$. However, the product $P_2P_3$ is a principal ideal, hence $[P_3] = [P_3']^{-1}$ and we may neglect $[P_3']$: the class group is generated by $[P_2]$ and $[P_3]$.
We claim that $P_2$ and $P_3$ are not principal. If $P_2$ is principal, then there exist $a, b \in \mathbb{Z}$ such that

$$2 = (a + b\sqrt{-14})^2 u$$

where $u$ is a unit. Taking norms we find

$$4 = \pm (a^2 + 14b^2)^2,$$

which is impossible, therefore $P_2$ is not principal. Suppose now that $P_3$ is principal, with $P_3 = O_K(a + b\sqrt{-14})$. There must be an element $c + d\sqrt{-14} \in P_3'$ such that

$$3 = (a + b\sqrt{-14})(c + d\sqrt{-14}).$$

Taking norms we find

$$9 = (a^2 + 14b^2)(c^2 + 14d^2),$$

which is impossible. So $P_3$ is not principal.

We now investigate the relation between the classes $[P_2]$ and $[P_3]$. We consider the principal ideal $I = O_K(2 + \sqrt{-14})$. As $\|I\| = N_{K/\mathbb{Q}}(2 + \sqrt{-14}) = 18 = 2 \cdot 3^2$, there must be a prime ideal containing 3 which divides $I$, i.e., $P_3$ divides $I$ or $P_3'$ divides $I$. However, $P_3$ and $P_3'$ cannot both divide $I$. If this is the case, then their product $O_K3$ divides $I$, which implies that 3 is a multiple of $2 + \sqrt{-14}$ (in $O_K$), which is not the case. Therefore only $P_3$ or $P_3'$ can divide $I$. Without loss of generality, let us suppose that $P_3$ divides $I$. We also notice that $\|P_3\| = 3$, because $\|O_K3\| = N_{K/\mathbb{Q}}(3) = 9$ and $\|O_K3\| = \|P_3\|\|P_3'\|$.

Since

$$[P_2][P_3]^2 = e \implies [P_3]^2 = [P_2]^{-1} = [P_2],$$

the class group is generated by $[P_3]$ and is cyclic. Also,

$$[P_3]^4 = [P_3]^2 = e \quad \text{and} \quad [P_3]^2 = [P_2] \neq e,$$

so the order of the group is 4.

Our next example provides a group of order 4 which is not cyclic.

**Example 4.** $K = \mathbb{Q}(\sqrt{-30})$

We begin by calculating the Minkowski bound:

$$\lambda = \frac{2}{\pi} \left( \frac{4}{\pi} \right)^\frac{3}{2} \sqrt[3]{30} = \frac{4}{\pi} \sqrt[3]{30} \quad \text{and} \quad 6 < \frac{4}{\pi} \sqrt[3]{30} < 7.$$
where \( u \) is a unit. Taking norms we obtain
\[
N_{K/Q}(2) = \pm N_{K/Q}(a + b\sqrt{-30})^2 \implies 4 = \pm (a^2 + 30b^2)^2,
\]
which is impossible. Thus \( P_2 \) is not principal; we show in an analogous manner that \( P_3 \) and \( P_5 \) are not principal. Therefore each of the elements \([P_2], [P_3] \) and \([P_5]\) are of order 2 in the class group.

Next we notice that
\[
P_2|O_K2, \quad P_3|O_K3, \quad P_5|O_K5 \implies P_2P_3P_5|O_K30,
\]
hence there exists an ideal \( Q \) such that \( P_2P_3P_5Q = O_K30 \). Taking norms we find
\[
2.3.5\|Q\| = 30 \implies \|Q\| = 1 \implies P_2P_3P_5 = O_K30.
\]
Therefore
\[
[P_2][P_3][P_5] = e \implies [P_2][P_3] = [P_3]^{-1} = [P_3],
\]
which implies that the group is generated by \([P_2]\) and \([P_3]\).

Our next step is to show that \([P_2]\) and \([P_3]\) are distinct. If \([P_2] = [P_3]\), then \([P_3] = [P_2]^2 = e\), which is false. Hence \([P_2] \neq [P_3]\) and so the group is generated by two distinct elements of order 2 and thus is isomorphic to a product of two cyclic groups of order 2.

We now consider a cubic number field, for which we will use some new ideas.

**Example 5.** \( K = \mathbb{Q}(\sqrt{2}) \)

We have already seen that the field \( K \) is monogenic. As usual we determine the Minkowski bound. There are three monomorphisms from \( K \) into \( \mathbb{C} \), namely the identity, which is real, and a pair of complex embeddings. We have
\[
\lambda = \frac{3!}{3^3}\left(\frac{4}{\pi}\right)^{1/2}108 = \frac{8}{9\pi}\sqrt{4.9.3} = \frac{16}{3\pi}\sqrt{3} \quad \text{and} \quad 6 < \frac{16}{\pi}\sqrt{3} < 7.
\]
Thus we consider the primes 2, 3 and 5. There is a unique prime ideal \( P_2 \) (resp. \( P_3 \)) containing 2 (resp. 3) and two prime ideals, \( P_5 \) and \( P_5' \), containing 5.

Let \( f = m(\sqrt{2}, Q) \). Then \( f(X) = -2 + X^2 \). As \( f \) is Eisenstein at 2, there exists a prime ideal \( P_2 \) in \( O_K \) such that \( O_K2 = P_2^3 \).

The reduction of \( f \) modulo 3 is \( f_3(X) = 1 + X^3 = (1 + X)^3 \), so there exists a prime ideal \( P_3 \) in \( O_K \) such that \( O_K3 = P_3^2 \).

The reduction of \( f \) modulo 5 is \( f_5(X) = -2 + X^3 = (-3 + X)(-1 + 3X + X^2) \). As \( g_2(X) = -1 + 3X + X^2 \) has no root in \( \mathbb{F}_5 \), \( g_2 \) is irreducible, hence there exist prime ideals \( P_5, P_5' \) in \( O_K \) such that that \( O_K5 = P_5P_5' \).

We claim that the prime ideals \( P_2, P_3, P_5 \) and \( P_5' \) are all principal. We set \( \alpha = \sqrt{2} \). Then
\[
8 = \|O_K\alpha\| = \|O_K\alpha\|^3 \implies \|O_K\alpha\| = 2.
\]
From Proposition 13.4 \( O_K\alpha \) is a prime ideal. Given that \( P_2 \) is the unique prime ideal in \( O_K \) lying over 2, we have \( P_2 = O_K\alpha \), i.e., \( P_2 \) is a principal ideal, as asserted.

For \( P_3 \) we proceed in a similar manner. We have
\[
27 = \|O_K3\| = \|O_K(1 + \alpha)\|^3 \implies \|O_K(1 + \alpha)\| = 3.
\]

284
Hence $O_K(1 + \alpha)$ is a prime ideal. Given that $P_3$ is the unique prime ideal in $O_K$ lying over 3, we have $P_3 = O_K(1 + \alpha)$, i.e., $P_3$ is a principal ideal.

Before considering $P_5$ and $P'_5$ we will establish a preliminary result.

**Lemma 19.1** If $K = \mathbb{Q}(\beta)$, $f = m(\beta, Q)$, $\deg(f) = d$ and $r \in Q$, then $f(r) = (-1)^d N_{K/Q}(\beta - r)$.

**Proof** First we notice that

$$f(X) = (-\beta_1 + X)(-\beta_2 + X)\cdots(-\beta_d + X),$$

where the $\beta_i$ are the conjugates of $\beta$. It follows that

$$f(X + r) = (-\beta_1 + r + X)(-\beta_2 + r + X)\cdots(-\beta_d + r + X).$$

As $f(X + r) = m(\beta - r, Q)$, the elements $\beta_1 - r, \ldots, \beta_d - r$ are the conjugates of $\beta - r$ and so, using Corollary 10.1, we have

$$f(r) = (-\beta_1 + r)(-\beta_2 + r)\cdots(-\beta_d + r) = (-1)^d N_{K/Q}(\beta - r),$$

as required. \qed

Now we turn to $P_5$ and $P'_5$. We suppose that $P_5$ corresponds to the factor $g_1(X) = -3 + X$ and $P'_5$ corresponds to $g_2$. Then $\|P_5\| = 5$ and $\|P'_5\| = 25$. From Lemma 19.1 we obtain

$$N_{K/Q}(\alpha + 2) = N_{K/Q}(\alpha - (-2)) = (-1)^3(-2 + (-2)^3) = 10 \Rightarrow O_K(2 + \alpha) = P_5 O_K \alpha,$$

because $P_5$ and $O_K \alpha$ are the only prime ideals in $O_K$ with respective norms 5 and 2. Therefore

$$P_5 = O_K(2 + \alpha) O_K(\frac{1}{\alpha}) = O_K(\frac{2}{\alpha} + 1) = O_K(\alpha^2 + 1).$$

We have shown that $P_5$ is principal. Now we consider $P'_5$. We have

$$O_K 5 = O_K(1 + \alpha^2) P'_5 = (1 + \alpha^2) P'_5,$$

so, from Lemma 12.3, $P'_5$ is principal.

As $P_2$, $P_3$, $P_5$ and $P'_5$ are all principal, the class group is trivial.

The following proposition summarizes the previous calculations:

**Proposition 19.1** We have:

- The ideal class group of $\mathbb{Q}(\sqrt{14})$ is trivial, hence the number ring of $\mathbb{Q}(\sqrt{14})$ is a PID;
- The ideal class group of $\mathbb{Q}(\sqrt{-5})$ is isomorphic to the cyclic group of order 2 $C_2$;
- The ideal class group of $\mathbb{Q}(\sqrt{-14})$ is isomorphic to the cyclic group of order 4 $C_4$;
- The ideal class group of $\mathbb{Q}(\sqrt{-30})$ is isomorphic to the product $C_2 \times C_2$;
- The ideal class group of $\mathbb{Q}(\sqrt{2})$ is trivial, hence the number ring of $\mathbb{Q}(\sqrt{2})$ is a PID.
There are various problems raised by the class number of a number field, some of which were originally considered by Gauss. Probably the most well-known of these is the Gauss Class Number Problem, namely to determine the imaginary quadratic number fields with class number 1. Gauss supposed that there were only nine such number fields: $\mathbb{Q}(\sqrt{k})$, with $k = -1, -2, -3, -7, -11, -19, -43, -67, -163$. This was subsequently proved in the 20th century (long after Gauss). There has also been work on determining the imaginary quadratic number fields with class number $n$, for certain other $n$.

Another question raised by Gauss is known as the Gauss Conjecture, namely $h(\mathbb{Q}(\sqrt{-d})) \to +\infty$ as $d \to +\infty$, where $h(\mathbb{Q}(\sqrt{-d}))$ denotes the class number of the number field $\mathbb{Q}(\sqrt{-d})$. This too was only proved in the 20th century. This result shows that there can only be a finite number of imaginary quadratic number fields with a fixed class number.

Gauss also conjectured that there is an infinite number of real quadratic number fields of class number 1. This has yet to be proved (or disproved).
Chapter 20

The distribution of ideals

Let \( K \) be a number field of degree \( n \) over \( \mathbb{Q} \). For each real number \( d > 0 \), we note \( i(d) \) the number of nonzero ideals \( I \) in \( \mathcal{O}_K \) with \( \|I\| \leq d \), which is finite by Theorem 13.5. For each ideal class \( C \) we write \( i_C(d) \) for the number of ideals \( I \) in \( C \) such that \( \|I\| \leq d \). In addition, Theorem 14.4 ensures that there is a finite number of ideal classes and so \( i(d) = \sum_C i_C(d) \). We aim to show that there is a constant \( k \), independent of \( C \), such that

\[
    i_C(d) = kd + O(d^{1 - \frac{1}{n}}). \tag{20.1}
\]

We will refer to this equation as the ideal counting equation. If \( h_K \) is the class number, then

\[
    i(d) = h_K kd + O(d^{1 - \frac{1}{n}}). \tag{20.2}
\]

Our treatment of the question is inspired from that in [15].

20.1 Transformation of the problem

We consider a class \( C \) and fix an ideal \( J \in C^{-1} \). Let \( A \) be the set of nonzero ideals in \( C \) with \( \|I\| \leq d \). We define an application \( \phi \) on \( A \) by multiplication by \( J \), i.e., for \( I \in A \), we set \( \phi(I) = IJ \). From Corollary 12.1 the mapping \( \phi \) is injective. Let \( B \) be the image of \( \phi \). We claim that \( B \) is the set of nonzero principal ideals \( (\alpha) \subset J \) satisfying the inequality \( \|(\alpha)\| \leq d\|J\| \).

There is no difficulty in seeing that \( IJ \) is a nonzero ideal included in \( J \) and, by the choice of \( J \), \( IJ \) is principal. If \( IJ = (\alpha) \), then

\[
    \|(\alpha)\| = \|IJ\| = \|I\|\|J\| \leq d\|J\|.
\]

Finally, suppose that \( (\alpha) \) is a nonzero principal ideal included in \( J \) with \( \|(\alpha)\| \leq d\|J\| \). Then \( J \) divides \( (\alpha) \), so there exists an ideal \( I \) such that \( IJ = (\alpha) \). In addition,

\[
    \|I\|\|J\| = \|IJ\| = \|(\alpha)\| \leq d\|J\|,
\]

from which we deduce that \( \|I\| \leq d \). This concludes the proof of our claim concerning \( B \).

To determine \( i_C(d) \), the number of elements in \( A \), given that there is a bijection from \( A \) onto \( B \), we may count the number of elements in \( B \). We notice that two nonzero principal ideals \( (\alpha) \) and \( (\beta) \) are the same if and only if \( \beta \) is a multiple of \( \alpha \) by a unit.
Let $D$ be any set of coset representatives of $U = U_K$ in $O_K^*$. The cardinal of $B$ is then the cardinal of the set of elements $\alpha$ in $D$ such that $\alpha \in J$ and $|N_{K/Q}(\alpha)| \leq d|J|$. Instead of using the set $D$ to determine $|B|$, we proceed indirectly.

Dirichlet’s unit theorem (Theorem 14.6) ensures that

$$U = W \times V,$$

where $W$ is the group of roots of unity of $K$ and $V$ a subgroup of $U$ generated by a fundamental system of $t = r + s - 1$ units. We set $w = |W|$. Let $D'$ be any set of coset representatives of $V$ in $O_K^*$. Then $w|B|$ is the cardinal of the set of $\alpha$ in $D'$ such that $\alpha \in J$ and $|N_{K/Q}(\alpha)| \leq d|J|$. Thus to determine $|B|$ we calculate $w|B|$.

### 20.2 Preliminary results

We begin with an elementary group result.

**Lemma 20.1** Let $G$ be a commutative semigroup and $G'$ an abelian group. We suppose that $f : G \to G'$ is multiplicative, i.e., $f(xy) = f(x)f(y)$, for $x, y \in G$, and that $S$ is a group included in $G$. Also, we suppose that $f$ restricted to $S$ is an isomorphism onto its image $S'$ in $G'$. If $D'$ is a set of coset representatives of $S'$ in $G'$, then $D = f^{-1}(D')$ is a set of coset representatives of $S$ in $G$. If $f$ is injective, then there is a bijection of $D'$ onto $D$.

**Proof** Let $z \in G$ and consider the coset $zS$. As $f(z)S'$ is a coset of $S'$ in $G'$, there exists $x' \in D'$ such that $f(z)S' = x'S'$. Thus there exists $w' \in S'$ such that $f(z)w' = x'$. However, there exists $w \in S$ such that $f(w) = w'$ and so $f(z)w' = f(z)f(w) = f(zw)$. Hence $zw \in f^{-1}(D') = D$. Therefore $zS$ has a representative in $D$.

Suppose now that there are two elements $x, y \in D$ representing the same coset $zS$. Then $x = zw_1$ and $y = zw_2$, with $w_1, w_2 \in S$ and we have

$$f(zw_1) = f(z)f(w_1) \quad \text{and} \quad f(zw_2) = f(z)f(w_2).$$

Since $f(w_1)$ and $f(w_2)$ lie in $S'$, $f(zw_1)$ and $f(zw_2)$ represent the same coset of $S'$ in $G'$. Let $x'$ be the representative of this coset in $D'$. Then

$$f(zw_1) = x' = f(zw_2) \implies f(w_1) = f(w_2).$$

As $f$ restricted to $S$ is an isomorphism, we have $w_1 = w_2$. Thus there is a unique representative of the coset $zS$ in $D$.

Suppose now that $f$ is injective and let $x' \in D'$. If $x_1, x_2 \in f^{-1}(x')$, then $f(x_1) = f(x_2)$. As $f$ is injective, we have $x_1 = x_2$. Thus the mapping $\phi : D' \to D, x' \mapsto f^{-1}(x')$ is well-defined. There is no difficulty in seeing that $\phi$ is bijective. \qed

**Remark** As a group is a semigroup, we may replace semigroup $G$ by group $G$ in the statement of the lemma.

For the second result we need some definitions. Let $[0, 1]^{n-1}$ denote the unit cube in $\mathbb{R}^{n-1}$. A function

$$f : [0, 1]^{n-1} \to \mathbb{R}^n$$

is said to be **Lipschitz** if there is a constant $\kappa$, referred to as a Lipschitz constant, such that

$$\|f(x) - f(y)\| \leq \kappa\|x - y\|,$$
for all \(x, y \in [0, 1]^{n-1}\), where \(\|\cdot\|\) denotes the length in \(\mathbb{R}^{n-1}\) or \(\mathbb{R}^n\). If \(B\) is a nonempty bounded region in \(\mathbb{R}^n\), then we say that the boundary \(\partial B\) of \(B\) is \((n-1)\)-Lipschitz parametrizable, or Lipschitz, if it can be covered by the images of a finite number of Lipschitz functions \(f : [0, 1]^{n-1} \rightarrow \mathbb{R}^n\).

Lemma 20.2 Let \(\Lambda\) be a lattice in \(\mathbb{R}^n\) and \(B\) a bounded set in \(\mathbb{R}^n\) whose boundary is \((n-1)\)-Lipschitz parametrizable. Then

\[
|\Lambda \cap aB| = \frac{\text{vol } B}{\det \Lambda} a^n + O(a^{n-1}),
\]

for a sufficiently large \(a\).

Proof Let us first suppose that \(\Lambda = \mathbb{Z}^n\). We will call a translate of the unit cube \([0, 1]^n\) whose centre is a point \(z\) of \(\mathbb{Z}^n\) an \(n\)-cube. We will write \(C(z)\) for such a cube. An \(n\)-cube contains a unique lattice point, namely its centre, and has volume \(1\). We may divide the \(n\)-cubes intersecting \(aB\) into two classes, namely those containing no boundary points of \(aB\) and those containing boundary points of \(aB\). We will write \(X\) for the set of \(n\)-cubes of the first type and \(Y\) for the set of \(n\)-cubes of the second type.

Together the sets \(X\) and \(Y\) form a covering of \(ab\) and so we have the the relation

\[
\text{vol } ab \leq |X| + |Y|.
\]

In addition, a lattice point in \(ab\) must lie either in an \(n\)-cube in \(X\) or in an \(n\)-cube in \(Y\). This implies that

\[
|\mathbb{Z}^n \cap ab| \leq |X| + |Y|.
\]

Putting these two relations together, we obtain

\[
-|Y| \leq |X| \leq \text{vol } ab \leq 0 \leq |\mathbb{Z}^n \cap ab| - |X| \leq |Y|,
\]

from which we deduce

\[
-|Y| \leq |\mathbb{Z}^n \cap ab| - \text{vol } ab \leq |Y| \quad \text{or} \quad ||\mathbb{Z}^n \cap ab| - \text{vol } ab| \leq |Y|.
\]

We aim now to estimate \(|Y|\). Unfortunately this is a quite arduous. The boundary of \(B\) is covered by a finite number of sets of the form \(f([0, 1]^{n-1})\), where \(f\) is a Lipschitz function. We may suppose that the functions all have the same Lipschitz constant \(\kappa\) (by taking, for example, the maximum of the constants). Then the boundary of \(ab\) is covered by the sets \(af([0, 1]^{n-1})\). We suppose that \(a \geq 1\) and subdivide the cube \([0, 1]^{n-1}\) into \([a]^{n-1}\) subcubes \(S\). The subcubes have side length \(\frac{1}{|a|}\). If \(x = (x_1, \ldots, x_{n-1}) \in [0, \frac{1}{|a|}]^{n-1}\), then

\[
x_1^2 + \cdots + x_{n-1}^2 \leq \frac{n-1}{|a|^2} \quad \Rightarrow \quad \|x\| \leq \frac{\sqrt{n-1}}{|a|},
\]

so the largest distance between two points in \(f(S)\) is \(\kappa \frac{\sqrt{n-1}}{|a|}\). This is the same for any of the small cubes \(S\) (by translation). It follows that the distance between two points in \(af(S)\) is at most \(a \kappa \frac{\sqrt{n-1}}{|a|} < 2\kappa \sqrt{n-1}\), because

\[
1 < a < |a| + 1 \Rightarrow \frac{a}{|a|} < 1 + \frac{1}{|a|} \leq 2.
\]
Thus we have a bound on the distance between pairs of points in $aB(S)$.

Our next step is to find a bound on the number of $n$-cubes $C(x)$ intersecting $aB(S)$. We fix a subcube $S$ and take a point $x \in aB(S)$. To simplify the notation, we set $h = 2\kappa \sqrt{n - 1}$. The closed ball of radius $h$ centered on $x$, which we note $B(x, h)$, contains $aB(S)$ and intersects a number of $n$-cubes bounded by $\mu = (2(h + \sqrt{n}))^n$. This last point needs an explanation. If $B(r, y)$ is a closed ball in $\mathbb{R}^n$, then

$$\text{vol } B(r, y) = \frac{\pi^{\frac{n}{2}} r^n}{\Gamma\left(\frac{n}{2} + 1\right)} = \frac{(\sqrt{\pi} r)^n}{\Gamma\left(\frac{n}{2} + 1\right)},$$

where $\Gamma$ denotes Euler’s gamma function. Now

$$\Gamma\left(\frac{n}{2} + 1\right) = \begin{cases} k! & \text{if } n = 2k, \\ \frac{(2k + 2)!}{(k + 1)!4^k\sqrt{\pi}} & \text{if } n = 2k + 1. \end{cases}$$

Thus, for $n \geq 2$ we have $\Gamma\left(\frac{n}{2} + 1\right) \geq 1$, and so $\text{vol } B(r, y) \leq (\sqrt{\pi} r)^n$. Now let $C(x)$ be an $n$-cube intersecting $B(x, h)$. Since the distance between two points in $C(x)$ is at most $\sqrt{n}$, if $y \in C(x)$, then $|y - x| \leq h + \sqrt{n}$, which implies that $C(x) \subset B(x, h + \sqrt{n})$. As

$$\text{vol } B(x, h + \sqrt{n}) \leq (\sqrt{\pi}(h + \sqrt{n}))^n < (2(h + \sqrt{n}))^n,$$

the number of $n$-cubes intersecting $B(x, h)$ is bounded by $\mu = (2(h + \sqrt{n}))^n$, as claimed. Since $aB(S) \subset B(x, h)$, the number of $n$-cubes intersecting $aB(S)$ is also bounded by $\mu$.

To conclude, we find a bound on the number of $n$-cubes intersecting the boundary $\partial(aB)$. Since there are $[a]^{n-1}$ cubes $S$, the boundary $\partial(aB)$ intersects at most $\mu[a]^{n-1}$ cubes. Given that $[a] \leq a$, the number of $n$-cubes intersecting $\partial(aB)$ is bounded by $\mu a^{n-1}$, i.e., $|Y|$ is bounded by $\mu a^{n-1}$. Hence we may write

$$|Z^n \cap aB| - \text{vol } aB| \leq |Y| \leq \mu a^{n-1},$$

where $\mu$ is a constant which is independent of $a$. From this we deduce

$$|Z^n \cap aB| = \text{vol } aB + (|Z^n \cap aB| - \text{vol } aB) = \text{vol } aB + O(a^{n-1}).$$

Since $\det Z^n = 1$ and $\text{vol } aB = a^n \text{vol } B$, we have

$$|Z^n \cap aB| = \frac{\text{vol } B}{\det Z^n} a^n + O(a^{n-1}),$$

as required.

We now consider the case where $\Lambda$ is a general lattice in $\mathbb{R}^n$. There exists a linear automorphism $L$ sending $\Lambda$ onto $Z^n$. Let $B' = L(B)$. We notice that $\partial B' = L(\partial B)$. If $f : [0, 1]^{n-1} \rightarrow \mathbb{R}^n$ is a Lipschitz mapping with constant $\kappa$, then $L \circ f$ is also Lipschitz with Lipschitz constant $\|L\| \kappa$. If $\partial B$ is covered by the images of the Lipschitz mappings $f_1, \ldots, f_m$, then $\partial B'$ is covered by the images of the Lipschitz mappings $L \circ f_1, \ldots, L \circ f_m$. Then,

$$Z^n \cap aB' = L(\Lambda) \cap aL(B) = L(\Lambda \cap aB) \implies |Z^n \cap aB'| = |\Lambda \cap aB|$$
and

$$|\Lambda \cap aB| = \frac{\text{vol } B'}{\det \mathbb{Z}^n} a^n + O(a^{n-1})$$

$$= \frac{\text{vol } L(B)}{\det L(\Lambda)} a^n + O(a^{n-1})$$

$$= \frac{\text{vol } B}{\det \Lambda} a^n + O(a^{n-1}),$$

as required. (To pass from the second line to the third, we have used Proposition G.2.)

### 20.3 Proof of the ideal counting equation: first steps

From Section 20.1 we need to find a set $D'$ of coset representatives $\alpha$ of $V$ in $O_K'$ and determine the cardinal of those $\alpha \in D'$ which belong to $J$ and satisfy the norm condition $|N_{K/Q}(\alpha)| \leq d|J|$. In fact, we will 'deplace' the problem to another context.

We define the mapping $\mu : O_K' \rightarrow \mathbb{R}^r \times \mathbb{C}^s$ by

$$\mu(\alpha) = (\sigma_1(\alpha), \ldots, \sigma_r(\alpha), \tau_1(\alpha), \ldots, \tau_s(\alpha)).$$

Then $\mu$ is a semigroup homomorphism, which is also injective. Let $V'$ be the image of $V$ in $\mathbb{R}^r \times \mathbb{C}^s$ and $Y$ a set of coset representatives of $V' = \mu(V)$ in $\mathbb{R}^r \times \mathbb{C}^s$. By Lemma 20.1, $X = \mu^{-1}(Y)$ is a set of coset representatives of $V$ in $O_K'$. However, we have two conditions on $X$ to take into account, namely

- 1. the norm condition $|N_{K/Q}(\alpha)| \leq d|J|$;
- 2. the inclusion of $\alpha$ in $J$.

From Lemma 14.1, $S(y) = N_{K/Q}(\alpha)$, where $y = \mu(\alpha)$, so we may take into account the norm condition by imposing that $|S(y)| \leq d|J|$. For the second condition we consider $\mathbb{R}^r \times \mathbb{C}^s$ as a subset of $\mathbb{R}^n$ and impose that $y \in \Lambda_J$, the lattice corresponding to $J$ in $\mathbb{R}^n$. Moreover, the set of $\alpha \in X$ such that $\alpha \in J$ and $|N_{K/Q}(\alpha)| \leq d|J|$ is in 1–1 correspondence with the set $T = \{ y \in Y : y \in \Lambda_J, |S(y)| \leq d|J| \}$ via the mapping $\alpha \mapsto \mu(\alpha)$. Thus $w|B|$ is the cardinal of $T$.

We now determine an appropriate set of coset representatives $Y$ of $V'$. To do so, we define a mapping $\text{Ln} : \mathbb{R}^r \times \mathbb{C}^s \rightarrow \mathbb{R}^{r+s}$ by

$$\text{Ln}(x_1, \ldots, x_r, z_1, \ldots, z_s) = (\ln |x_1|, \ldots, \ln |x_r|, 2\ln |z_1|, \ldots, 2\ln |z_s|).$$

We notice that $\text{Ln}(xy) = \text{Ln}(x) + \text{Ln}(y)$, hence $\text{Ln}$ defines a group homomorphism into $(\mathbb{R}^{r+s}, +)$. We also observe that $\text{Ln} \circ \mu$ is the mapping $\lambda$ which we defined in Section 14.4. The image of $\lambda$ restricted to $U_K$ spans the hyperplane

$$H = \{ (x_1, \ldots, x_{r+s}) \in \mathbb{R}^{r+s} : \sum_{i=1}^{r+s} x_i = 0 \}.$$  

Since $V$ is a subgroup of $U_K$, $F = \lambda(V) = \text{Ln}(V')$ is also an additive subgroup of $H$. As $\mu$ defines an isomorphism from $V$ onto $V'$, $\text{Ln}$ restricted to $V'$ can be written $\text{Ln} = \lambda \circ \mu^{-1}$ and
it follows that $\text{Ln}$ defines an isomorphism from $V'$ onto $F$, because $\lambda : V \rightarrow F$ is an isomorphism.

We need to justify the last statement, namely that $\lambda$ restricted to $V$ is injective. We recall that $\lambda$ is a mapping from $O_K$ into $\mathbf{R}^{r+s}$, which defines a group homomorphism when restricted to $U_K$, the group of units in $K$. The kernel of $\lambda$ is $W$, the set of roots of unity in $K$. Also $U_K$ is the direct product of $W$ and a subgroup $V$ generated by a set of fundamental units. If $x \in V$ and $\lambda(x) = 0$, then $x \in W \cap V$, which implies that $x = 1$. It follows that $\lambda$ is injective.

We now set $u = (1, \ldots, 1, 2, \ldots, 2)$. As $u \notin H$, we may write

$$R^{r+s} = H \oplus Ru.$$  

To simplify the notation, let us set $v_i = \lambda(\epsilon_i)$, for $i = 1, \ldots, t$, where $\{\epsilon_1, \ldots, \epsilon_t\}$ is a fundamental system of units of $V$. We recall that the $v_i$ form a basis of the hyperplane $H$ (see Theorem 14.6).

We now set

$$\Pi = \{w \in R^{r+s} : w = \sum_{i=1}^{t} a_i v_i : 0 \leq a_i < 1\}.$$  

Then $\Pi \oplus Ru$ is a set of coset representatives $Z$ of the subgroup $F$ in $R^{r+s}$. Using Lemma 20.1 again, if we set $Y = \text{Ln}^{-1}(Z)$, then $Y$ is a set of coset representatives of $V'$ in $R^{r} \times C^{s*}$.

We need to justify that $\Pi \oplus Ru$ is in fact a set of coset representatives of the subgroup $F$ in $R^{r+s}$. If $x \in R^{r+s}$, then

$$x = \sum_{i=1}^{t} a_i v_i + au,$$

with $a_i, a \in \mathbf{R}$. We may write $\tilde{a}_i = |a_i| + a_i$, where $0 \leq a_i < 1$. Then

$$x = \sum_{i=1}^{t} a_i v_i + au + \sum_{i=1}^{t} |a_i| v_i.$$

As the last term in the expression belongs to $F$, the elements of $\Pi \oplus Ru$ form a set of coset representatives of $F$ in $R^{r+s}$, as claimed.

We now observe that $Y$ is homogeneous, i.e., if $a \in \mathbf{R}^s$, then $ay = Y$. To see this, let $y = (x_1, \ldots, x_r, z_1, \ldots, z_s) \in Y$ and $a \in \mathbf{R}^s$. Then

$$\text{Ln}(ay) = (\ln |ax_1|, \ldots, \ln |ax_r|, 2\ln |az_1|, \ldots, 2\ln |az_s|)$$

$$= \ln |a|u + (\ln |x_1|, \ldots, \ln |x_r|, 2\ln |z_1|, \ldots, 2\ln |z_s|),$$

which clearly lies in $Z$. So $ay \subset Y$. On the other hand, if $y \in Y$, then $\frac{1}{a}y \in Y$, which implies that $y = a \cdot \frac{1}{a}y \in aY$. Hence $Y \subset aY$ and it follows that $aY = Y$, as claimed. For $a > 0$, we define

$$Y_a = \{y \in Y : |S(y)| \leq a\}.$$  

Using the homogeneity of $Y$, we easily obtain the equality

$$Y_a = \sqrt{a}Y_1.$$  

292
If $Y_1$ is bounded and has a Lipschitz boundary, then we may apply Lemma 20.2 to deduce that
\[ |\Lambda_J \cap \sqrt[d]{d} \| J \| \| Y_1 \| = \frac{\text{vol } Y_1}{\det \Lambda_J} d + O \left( \left( \| J \| \right)^{1 - \frac{1}{d}} \right) = \frac{\text{vol } Y_1}{\det \Lambda} d + O(d^{1 - \frac{1}{d}}), \]
because $\| J \| = \frac{\det \Lambda_J}{\det \Lambda}$ (cf. end of Section 14.1). Our aim is to estimate the cardinal of the set $T = \{ y \in Y : y \in \Lambda_J, |S(y)| \leq d \| J \| \}$. Now
\[ T = \Lambda_J \cap \{ y \in Y : |S(y)| \leq d \| J \| \} = \Lambda_J \cap \sqrt[d]{d} \| J \| \| Y_1 \|, \]
therefore, under the conditions on $Y_1$, we obtain
\[ |T| = |\Lambda_J \cap \sqrt[d]{d} \| J \| \| Y_1 \|| = \frac{\text{vol } Y_1}{\det \Lambda} d + O(d^{1 - \frac{1}{d}}). \]
Thus
\[ i_C(d) = kd + O(d^{1 - \frac{1}{d}}), \]
where $k = \frac{\text{vol } Y_1}{\det \Lambda}$. 

In the next section we will show that $Y_1$ is in fact bounded and has a Lipschitz boundary.

### 20.4 Properties of the set $Y_1$

We now show that $Y_1$ has the desired properties, namely that $Y_1$ is bounded and has a Lipschitz boundary. First we find a useful representation of $Y_1$. By definition, $Y_1$ consists of those elements $y = (x_1, \ldots, x_r, z_1, \ldots, z_s) \in \mathbb{R}^{r \times s} \times \mathbb{C}^{s^s}$ such that
\[ \ln(y) = (\ln |x_1|, \ldots, \ln |x_r|, 2 \ln |z_1|, \ldots, 2 \ln |z_s|) \in \Pi \oplus \mathbb{R} u, \]
with $|x_1 \cdots x_r z_1^2 \cdots z_s^2| \leq 1$. The last condition is equivalent to saying that
\[ \ln |x_1| + \cdots + \ln |x_r| + 2 \ln |z_1| + \cdots + 2 \ln |z_s| \leq 0. \]
Writing $v_i^{(1)}, \ldots, v_i^{(r+s)}$ for the coordinates of $v_i$, we have the system of equations
\[ \begin{align*}
\ln |x_1| &= a_1 v_1^{(1)} + \cdots + a_t v_t^{(1)} + b \\
\vdots &= \vdots \\
\ln |x_r| &= a_1 v_1^{(r)} + \cdots + a_t v_t^{(r)} + b \\
2 \ln |z_1| &= a_1 v_1^{(r+1)} + \cdots + a_t v_t^{(r+1)} + b2 \\
\vdots &= \vdots \\
2 \ln |z_s| &= a_1 v_1^{(r+s)} + \cdots + a_t v_t^{(r+s)} + b2,
\end{align*} \]
where the $a_i$ and $b$ are elements of $\mathbb{R}$. Since the $v_i$ belong to $H$, the sum of their coefficients has the value 0 and it follows that $b$ is bounded above by 0 if and only if the sum of the coefficients of $\ln(y)$ is bounded above by 0. From this we deduce $Y_1$ is composed of those $y \in \mathbb{R}^{r \times s} \times \mathbb{C}^{s^s}$ such that $\ln(y) \in \Pi \oplus (-\infty, 0) u$.

We now may show that $Y_1$ is a bounded set. For $j = 1, \cdots, r$, the sum $\sum_{i=1}^t a_i v_i^{(j)}$ is bounded, because $|\sum_{i=1}^t a_i v_i^{(j)}| \leq \sum_{i=1}^t |v_i^{(j)}|$. As $b \leq 0$, $\ln |x_i|$ is bounded above, which implies that $|x_i|$ is
bounded above. In the same way, for \( j = 1, \ldots, s \), \(|z_j|\) is bounded above, so the set \( Y_1 \) is bounded.

We note \( Y_1^+ \) the subset of \( Y_1 \) whose real coordinates \( x_1, \ldots, x_r \) are positive. We claim that \( Y_1 \) has a Lipschitz boundary, if \( Y_1^+ \) has a Lipschitz boundary. To prove this, we need a preliminary result.

**Lemma 20.3** If \( A_1, \ldots, A_m \) are subsets of a topological space \( T \), then \( \partial(A_1 \cup \cdots \cup A_m) \subseteq \partial A_1 \cup \cdots \cup \partial A_m \), where \( \partial X \) denotes the boundary of a set \( X \).

**Proof** We use a proof by induction. For \( m = 2 \) we have

\[
\partial(A_1 \cup A_2) = \overline{A_1 \cup A_2 \cap \overline{A_1 \cup A_2}} = \overline{A_1 \cup A_2 \cap \overline{A_1} \cap \overline{A_2}} = \overline{(A_1 \cap \overline{A_2}) \cap \overline{A_1} \cap \overline{A_2}}
\]

In the third line we used the fact that if \( A \) and \( B \) are subsets of a topological space, then \( \overline{A \cup B} = \overline{A} \cup \overline{B} \). Here is a proof. First, \( A \subset A \cup B \) implies that \( \overline{A} \subset \overline{A \cup B} \). In the same way, \( \overline{B} \subset \overline{A \cup B} \), so \( \overline{A \cup B} \subset \overline{A} \cup \overline{B} \). Now, \( \overline{A \cup B} \) contains \( A \) and \( B \), therefore \( A \cup B \subset \overline{A \cup B} \); as \( \overline{A \cup B} \) is closed, \( \overline{A} \cup \overline{B} \subset \overline{A \cup B} \).

Suppose now that the result is true up to \( m \) and consider the case \( m + 1 \). We have

\[
\partial(A_1 \cup \cdots \cup A_m \cup A_{m+1}) \subseteq \partial(A_1 \cup \cdots \cup A_m) \cup \partial A_{m+1} \subseteq \partial A_1 \cup \cdots \cup \partial A_m \cup \partial A_{m+1}.
\]

Hence the result is true up to \( m + 1 \), so, by induction, the result is true for all \( m \geq 2 \). \( \square \)

**Lemma 20.4** If \( Y_1^+ \) has a Lipschitz boundary, then \( Y_1 \) also has a Lipschitz boundary.

**Proof** Suppose that \( Y_1^+ \) has a Lipschitz boundary. The real coordinates of the elements of \( Y_1 \) may be positive or negative. We divide \( Y_1 \) into subsets having the same signs on the \( x_i \), for example, \( x_1 < 0, x_2 > 0, \ldots, x_r > 0 \) or \( x_1 > 0, x_2 > 0, x_3 < 0, x_4 > 0, \ldots, x_r > 0 \). With \( x_1 > 0 \), for all \( i \), we have \( Y_1^+ \). There are \( 2^r \) such subsets. If \( S \) is one of these subsets, then there is a linear automorphism \( L \) of \( \mathbb{R}^r \times \mathbb{C}^r \) taking \( Y_1^+ \) onto \( S \). The isomorphism \( L \) maps the boundary of \( Y_1^+ \) onto that of \( S \). If \( f \) is a Lipschitz function covering part of the boundary of \( Y_1^+ \), then \( L \circ f \) is a Lipschitz function covering the corresponding part of the boundary of \( S \). It follows that \( S \) has a Lipschitz boundary. From Lemma 20.3, the boundary of \( Y_1 \) is contained in the union of the boundaries of the subsets \( S \) and hence is Lipschitz. \( \square \)

We now concentrate our attention on the set \( Y_1^+ \).

**Proposition 20.1** The set \( Y_1^+ \) has a Lipschitz boundary.

**Proof** We recall that we set \( v_i = \lambda(\epsilon_i) \), where \( \{\epsilon_1, \ldots, \epsilon_l\} \) is a system of fundamental units in \( O_K \). As above, for each \( v_i \), we write \( v_i^{(1)}, \ldots, v_i^{(r+s)} \) for its coordinates. A point \( y = \)
\((x_1, \ldots, x_r, z_1, \ldots, z_s) \in Y_1^+\) is characterized by the equations

\[
\ln(x_1) = \sum_{i=1}^t a_i v_i^{(1)} + b
\]

\[
\vdots
\]

\[
\ln(x_r) = \sum_{i=1}^t a_i v_i^{(r)} + b
\]

\[
2 \ln |z_1| = \sum_{i=1}^t a_i v_i^{(r+1)} + 2b
\]

\[
\vdots
\]

\[
2 \ln |z_s| = \sum_{i=1}^t a_i v_i^{(r+s)} + 2b,
\]

where the \(x_j\) are positive, the \(z_k\) are nonzero, the \(a_i\) belong to the interval \([0, 1)\) and \(b\) is an element of \((-\infty, 0]\).

Now we set \(a_{r+s} = e^b\) and write \(z_k = \rho_k e^{i \theta_k}\). Then we have the relations

\[
x_j = a_{r+s} \exp\left(\sum_{i=1}^t a_i v_i^{(j)}\right)
\]

\[
\rho_k = a_{r+s} \exp\left(\frac{1}{2} \sum_{i=1}^t a_i v_i^{(r+k)}\right)
\]

\[
\theta_k = 2\pi a_{r+s+k},
\]

with \(a_{r+s} \in (0, 1]\), because \(b \in (-\infty, 0]\), and all the other \(a_i \in [0, 1)\). We define the "polar coordinate" transformation \(\beta\) by

\[
\beta(x_1, \ldots, x_r, \rho_1, \ldots, \rho_s, \theta_1, \ldots, \theta_s) = (x_1, \ldots, x_r, \rho_1 e^{i \theta_1}, \ldots, \rho_s e^{i \theta_s})
\]

and set \(f = \beta \circ \alpha\), where

\[
\alpha(a_1, \ldots, a_n) = \left(a_{r+s} \exp\left(\sum_{i=1}^t a_i v_i^{(1)}\right), \ldots, a_{r+s} \exp\left(\sum_{i=1}^t a_i v_i^{(r)}\right),
\right.
\]

\[
a_{r+s} \exp\left(\frac{1}{2} \sum_{i=1}^t a_i v_i^{(r+1)}\right), \ldots, a_{r+s} \exp\left(\frac{1}{2} \sum_{i=1}^t a_i v_i^{(r+s)}\right),
\]

\[
2\pi a_{r+s+1}, \ldots, 2\pi a_{r+2s}\).
\]

Letting the \(a_i\) vary, we obtain a continuous injective mapping \(f\) from \(C = [0, 1]^t \times (0, 1] \times [0, 1]^s\) onto \(Y_1^+\). Before continuing we recall a generalization of the mean value theorem:

Let \(E\) and \(F\) be normed vector spaces, \(O\) an open subset of \(E\) and \(h: O \to F\) differentiable on \(O\). If the segment \([a, b]\) is contained in \(O\), then

\[
\|h(b) - h(a)\| \leq \sup_{x \in [a, b]} \|dh_x\| \|b - a\|.
\]

295
If \( O \) is not only open but also convex and the norm of the differential is bounded on \( O \), then \( h \) is Lipschitz on \( O \). (The convexity ensures that any two points \( a, b \in O \) can be joined by a segment in \( O \).)

The function \( f \) which we defined above may be extended to \( \mathbb{R}^n \) and has continuous partial derivatives, so is of class \( C^1 \), i.e., the differential is defined and continuous on \( \mathbb{R}^n \). Let \( \epsilon > 0 \) and \( O = (-\epsilon, 1 + \epsilon)^n \). Then \( O \) is a convex open subset in \( \mathbb{R}^n \). On the set \( \tilde{O} = [-\epsilon, 1 + \epsilon]^n \), the closure of \( O \), the norm of the differential is bounded, because \( \tilde{O} \) is compact, hence the norm of the differential is bounded on \( O \) and so \( f \) is Lipschitz on \( O \). It follows that \( f \) is Lipschitz on \([0,1]^n\), being a subset of \( O \).

We claim that \( f([0,1]^n) \) is \( \overline{Y}_1^+ \). To see this, we notice first that, as \([0,1]^n\) is compact and \( f \) continuous, \( f([0,1]^n) \) is compact and therefore closed. Given that \( Y_1^+ \subset f([0,1]^n) \), we have \( \overline{Y}_1^+ \subset f([0,1]^n) = \overline{f(C)} \). However, \( Y_1^+ = f(C) \) implies that \( \overline{Y}_1^+ = \overline{f([0,1]^n)} \), as claimed.

We are now in a position to show that the boundary of \( Y_1^+ \) is Lipschitz. The closure \( \overline{Y}_1^+ \) is the disjoint union of the interior \( Y_1^{+0} \) and the boundary \( \partial Y_1^+ \). We will show that \( f \) maps the interior of the \( n \)-cube \([0,1]^n\) into the interior \( Y_1^{+0} \), which implies that the boundary of the \( n \)-cube \([0,1]^n\) is mapped onto a set containing the boundary \( \partial Y_1^+ \). Since the boundary of \([0,1]^n\) may be considered as composed of \( 2n \) \((n-1)\)-cubes, namely the sides of the \( n \)-cube \([0,1]^n\), the boundary \( \partial Y_1^+ \) is covered by the images of \( 2n \) Lipschitz mappings defined on \([0,1]^{n-1}\) (the restrictions of \( f \) to the sides of \([0,1]^n\)) and so is Lipschitz. It remains to show that the interior \((0,1)^n\) of \([0,1]^n\) is in fact mapped into the interior \( Y_1^{+0} \).

The mapping \( f \) restricted to \((0,1)^n\) is the composition of the following four mappings:

\[
    f_1 : (0,1)^n \rightarrow \mathbb{R}^n, (t_1, \ldots, t_n) \mapsto (t_1, \ldots, \ln(t_{r+s}), \ldots, t_n),
\]

\[
    f_2 : \mathbb{R}^n \rightarrow \mathbb{R}^n, (u_1, \ldots, u_n) \mapsto (u_1, \ldots, u_n)M,
\]

where

\[
    M = \begin{pmatrix}
        v_1^{(1)} & \ldots & v_1^{(r+s)} \\
        \vdots & & \vdots \\
        v_t^{(1)} & \ldots & v_t^{(r+s)} \\
        1 & \ldots & 2 \\
        0 & \ldots & \mathbf{I}_s
    \end{pmatrix},
\]

\[
    f_3 : \mathbb{R}^n \rightarrow \mathbb{R}^n, (a_1, \ldots, a_n) \mapsto (e^{a_1}, \ldots, e^{a_{r+s+1}}, \ldots, 2\pi a_{r+s+1}, \ldots, 2\pi a_n),
\]

and

\[
    f_4 : \mathbb{R}^r \times (0,\infty)^s \times \mathbb{R}^s \rightarrow \mathbb{R}^r \times \mathbb{C}^s,
\]

\[
    (x_1, \ldots, x_r, \rho_1, \ldots, \rho_s, \theta_1, \ldots, \theta_s) \mapsto (x_1, \ldots, x_r, \rho_1 e^{i\theta_1}, \ldots, \rho_s e^{i\theta_s}).
\]

(The first \( r \) coordinates in the line \( 1 \ldots 2 \) of the matrix \( M \) have the value \( 1 \) and the remaining \( s \) coordinates the value \( 2 \).) Of course, the mapping \( f_4 \) is just the "polar coordinate" transformation defined above.
We claim that the four mappings are open and so their composition \( f \) is also open. As the matrix \( M \) is invertible, \( f_2 \) is an automorphism, hence open. To show that the other three mappings are open, we recall another result from analysis, namely the inverse mapping theorem:

Let \( E \) and \( F \) be Banach spaces, \( O \) an open subset of \( E \) and \( h : O \rightarrow F \) of class \( C^1 \). If \( x \in O \) and the differential \( dh_x \) is invertible, then there is an open neighbourhood \( O' \) of \( x \) contained in \( O \) such that \( h|_{O'} \) is a \( C^1 \)-diffeomorphism onto its image. This implies that \( h(O') \) is an open subset of \( F \).

If the differential \( dh_x \) is invertible at every point \( x \in O \), then for every point \( x \in O \) there is an open neighbourhood \( O_x' \) of \( x \) contained in \( O \) such that \( h|_{O_x'} \) is a \( C^1 \)-diffeomorphism onto its image. This implies that \( h(O_x') \) is an open subset of \( F \).

To see that the mappings \( f_1, f_3 \) and \( f_4 \) are open, it is sufficient to show that the differential \( df_{ix} \) is invertible on each point \( x \) of the domain of \( f_i \). (The functions \( f_i \) have continuous partial derivatives and so are of class \( C^1 \).) To determine whether \( df_{ix} \) is invertible, we may consider the invertibility of the Jacobian matrix \( J_{f_i}(x) \). This is the case for all four mappings. For example, the Jacobian matrix of \( f_1 \) has the form

\[
J_{f_1}(t_1, \ldots, t_n) = \begin{pmatrix} I_t & 0 & 0 \\ 0 & t_{r+s}^{-1} & 0 \\ 0 & 0 & I_s \end{pmatrix},
\]

which is clearly invertible. We leave the calculation of the determinant of the Jacobian matrix of \( f_3 \) and \( f_4 \) to the reader. (In the case of \( f_4 \), we consider \( \rho_j e^{i \theta_j} \) as the pair \( (\rho_j \cos \theta_j, \rho_j \sin \theta_j) \).)

We have shown that the four mappings \( f_1, f_2, f_3 \) and \( f_4 \) are open, hence \( f \) restricted to \( (0, 1)^n \) is an open mapping. It follows that the image of \( f \) restricted \( (0, 1)^n \) is an open subset of \( Y_1^+ \) and thus is contained in \( Y_1^{+0} \), as asserted. Hence the boundary of \( Y_1^+ \) is Lipschitz, as required. \( \square \)

To sum up, we have

**Theorem 20.1** The boundary of \( Y_1^+ \) is Lipschitz and hence that of \( Y_1 \) is Lipschitz.

### 20.5 The constant \( k \)

There is a point we have glossed over. We saw above that \( k = \frac{\text{vol } Y_1}{\det A} \). However, \( \text{vol } Y_1 \) could depend on the system of fundamental units which we choose. We aim to show that this choice in fact has no effect on \( \text{vol } Y_1 \) and hence no effect on \( k \). We will calculate explicitly \( \text{vol } Y_1 \) in passing by \( \text{vol } Y_1^+ = 2^r \text{vol } Y_1^+ \) and show that this is independant of the choice of the set of fundamental units.

To calculate the volume \( \text{vol } Y_1^+ \) we aim to use the "change of variables" formula:
Let $O$ be an open subset of $\mathbb{R}^n$ and $f : O \to \mathbb{R}^n$ an injective, continuously differentiable mapping such that $J_f(x) \neq 0$, for all $x \in O$. If $g : f(O) \to \mathbb{R}$ is integrable, then

$$\int_{f(O)} g \, dx = \int_O (g \circ f) |J_f| \, dx.$$ 

A proof may be found, for example, in [24].

Applying this result, with $O = (0,1)^n$, $f$ as defined above and $g$ the characteristic function of $Y_1^+$, we obtain

$$\text{vol } Y_1^+ = \int_{(0,1)^n} |J_f| \, dx,$$

so we need to determine the Jacobian matrix of $f$.

We recall that $f$ is the composition of two mappings $\beta$ and $\alpha$, defined in the previous section, i.e., $f = \beta \circ \alpha$. The Jacobian matrix of $f$ is the product of the Jacobian matrices of $\beta$ and $\alpha$, i.e., $J_f = J_\beta \circ J_\alpha$. (We draw attention to the fact that we consider $\rho_j e^{i\theta_j}$ as the pair $(\rho_j \cos \theta_j, \rho_j \sin \theta_j) \in \mathbb{R}^2$.) The Jacobian matrix $J_\beta$ is easy to determine and we obtain $|\det J_\beta| = \rho_1 \cdots \rho_s$. To find the Jacobian matrix $J_\alpha$ we calculate the partial derivatives of $x_j$, $\rho_j$ and $\theta_j$, with respect to the $a_i$, using the relations (21.3), (21.4) and (21.5). We obtain

$$\frac{\partial x_j}{\partial a_i} = \begin{cases} x_j v_i^{(j)} & \text{if } 1 \leq i < r + s \\ \frac{x_j}{a_{r+s}} & \text{if } i = r + s \\ 0 & \text{if } r + s < i \leq n, \end{cases}$$

$$\frac{\partial \rho_j}{\partial a_i} = \begin{cases} \frac{1}{2} \rho_j v_i^{(r+j)} & \text{if } 1 \leq i < r + s \\ \frac{\rho_j}{a_{r+s}} & \text{if } i = r + s \\ 0 & \text{if } r + s < i \leq n \end{cases}$$

and

$$\frac{\partial \theta_j}{\partial a_i} = \begin{cases} 2\pi & \text{if } i = r + s + j \\ 0 & \text{otherwise}. \end{cases}$$

Writing this in matrix form, we have

$$J_\alpha = \begin{pmatrix} v_1^{(1)} x_1 & \cdots & v_1^{(1)} x_1 & \frac{x_1}{a_{r+s}} & & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdOTS
where $M$ is the matrix defined in the previous section. Hence

$$\left| \det J_f \right| = \frac{x_1 \cdots x_r \rho_1^2 \cdots \rho_s^2 \pi^s}{a_{r+s}} \left| \det M \right| = \left| \det M \right| \pi^s a_{r+s}^{n-1}.$$ 

(The last equality needs an explanation. From the equations (21.3), (21.4) and (21.5) we have

$$x_1 \cdots x_r \rho_1^2 \cdots \rho_s^2 = a_{r+s} \exp \left( \sum_{i=1}^{t} a_i \epsilon_i^{(1)} \right) \cdots \exp \left( \frac{1}{2} \sum_{i=1}^{t} a_i \epsilon_i^{(r+s)} \right) \cdots$$

$$= a_{r+s} \exp(a_1(\epsilon_1^{(1)} + \cdots + \epsilon_1^{(r+s)}) \cdots \exp(a_t(\epsilon_t^{(1)} + \cdots + \epsilon_t^{(r+s)}))$$

$$= a_{r+s} \exp(0) \cdots \exp(0) = a_{r+s},$$

because the vectors $\epsilon_i$ belong to the hyperplane $H.$)

Therefore

$$\text{vol } Y_1^+ = \int_{(0,1)^n} |J_f(a_1, \ldots, a_n)| da_1 \cdots da_n$$

$$= \left| \det M \right| \pi^s \int_{(0,1)^n} a_{r+s}^{n-1} da_1 \cdots da_n$$

$$= \frac{\left| \det M \right| \pi^s}{n}$$

and it follows that

$$\text{vol } Y_1 = 2^n \frac{\left| \det M \right| \pi^s}{n}.$$

The matrix $M$ may vary according to the choice of the fundamental system of units. We claim that this does not affect the absolute value of the determinant. Suppose that $\{\epsilon_1, \ldots, \epsilon_t\}$ and $\{\epsilon'_1, \ldots, \epsilon'_s\}$ are fundamental systems of units. Then each $\epsilon'_i$ may be written

$$\epsilon'_i = \zeta_i \epsilon_1^{n_{i,1}} \cdots \epsilon_t^{n_{i,t}},$$

a where $\zeta_i$ is a root of unity and $n_{i,1}, \ldots, n_{i,t} \in \mathbb{Z}.$ Thus

$$v'_i = \lambda(\epsilon'_i) = n_{i,1} \lambda(\epsilon_1) + \cdots + n_{i,t} \lambda(\epsilon_t) = n_{i,1} v_1 + \cdots + n_{i,t} v_2.$$

If we note $M$ and $M'$ the matrices corresponding respectively to $\{\epsilon_1, \ldots, \epsilon_t\}$ and $\{\epsilon'_1, \ldots, \epsilon'_s\},$ then we have

$$M' = \begin{pmatrix} n_{1,1} & \cdots & n_{1,t} \\ \vdots & \ddots & \vdots \\ n_{t,1} & \cdots & n_{t,t} \\ 0 & \cdots & 0 \end{pmatrix} \begin{pmatrix} 0 \\ \vdots \\ 0 \end{pmatrix} = P M.$$ 

In the same way, there exists a matrix $Q$ with integer coefficients such that $M = Q M'.$ Therefore $P$ is invertible, with inverse $Q.$ As the determinants of $P$ and $Q$ are integers, we must have $\det P = \pm 1$ and $\det Q = \pm 1.$ It follows that

$$\left| \det M' \right| = \left| \det M \right| \left| \det P \right| = \left| \det M \right|.$$

Therefore $\text{vol } Y_1$ is independent of the fundamental system of units and so is the constant $k.$ We call the expression $\frac{1}{n} |M|$ the regulator of $O_K$ (or $K$) and we note it $\text{reg}(O_K).$ Then

$$k = \frac{\text{vol } Y_1}{w \det \Lambda} = \frac{2^r \pi^s \text{reg}(O_K)}{w 2^{-s} \sqrt{\text{disc}(O_K)}} = \frac{2^{r+s} \pi^s \text{reg}(O_K)}{w \sqrt{\text{disc}(O_K)}}.$$
It is interesting to determine the value of $k$ when $K$ is a quadratic number field. First we consider the case where $K = \mathbb{Q}(\sqrt{m})$ is imaginary. As we saw in Section 14.4, the units are the roots of unity, so we may replace $w$ by $|U_K|$. We also saw in Section 14.4 that $s = 1$ and $r = 0$, so $t = r + s - 1 = 0$. Setting $\text{reg}(O_K) = 1$, we have

$$k = \frac{2\pi}{|U_K| \sqrt{|\text{disc}(O_K)|}}.$$ 

Now we consider a real quadratic number field $K = \mathbb{Q}(\sqrt{m})$. We have two cases to consider, namely $m \equiv 2, 3 \pmod{4}$ and $m \equiv 1 \pmod{4}$.

Case 1: $m \equiv 2, 3 \pmod{4}$ The algebraic integers are of the form $x = a + b\sqrt{m}$, with $a, b \in \mathbb{Z}$. The units are those whose norm is $\pm 1$, i.e., $a^2 - b^2m = \pm 1$. There are two embeddings of $K$ into $\mathbb{R}$:

$$\sigma_1(a + b\sqrt{m}) = a + b\sqrt{m} \quad \text{and} \quad \sigma_2(a + b\sqrt{m}) = a - b\sqrt{m}.$$ 

Let $u > 0$ be a fundamental unit, with $u = a' + b'\sqrt{m}$. Then $\sigma_1(u) = u$ and $\sigma_2(u) = a' - b'\sqrt{m}$. However,

$$(a' + b'\sqrt{m})(a' - b'\sqrt{m}) = a'^2 - b'^2m = \pm 1,$$

because $u$ is a unit. Hence $\sigma_2(u) = \pm u^{-1}$ and it follows that $\ln|\sigma_2(u)| = \ln u^{-1} = -\ln u$. Therefore

$$M = \begin{pmatrix} \ln u & -\ln u \\ 1 & 1 \end{pmatrix},$$

therefore $\det M = 2\ln u$ and so $\text{reg}(O_K) = \ln u$.

Case 2: $m \equiv 1 \pmod{4}$ The algebraic integers are of the form $x = \frac{1}{2}(a + b\sqrt{m})$, where $a, b \in \mathbb{Z}$ and have the same parity. Since the norm of $x$ is $\frac{1}{4}(a^2 - mb^2)$, $x$ is a unit if and only if $a^2 - mb^2 = \pm 4$, with $a$ and $b$ both odd or both even. There are two embeddings of $K$ into $\mathbb{R}$:

$$\sigma_1\left(\frac{1}{2}(a + b\sqrt{m})\right) = \frac{1}{2}(a + b\sqrt{m}) \quad \text{and} \quad \sigma_2\left(\frac{1}{2}(a + b\sqrt{m})\right) = \frac{1}{2}(a - b\sqrt{m}).$$

Let $u > 0$ be a fundamental unit, with $u = \frac{1}{2}(a' + b'\sqrt{m})$. Then $\sigma_1(u) = u$ and $\sigma_2(u) = \frac{1}{2}(a' - b'\sqrt{m})$. However,

$$\frac{1}{2}(a' + b'\sqrt{m})\frac{1}{2}(a' - b'\sqrt{m}) = \frac{1}{4}(a'^2 - b'^2m) = \pm 1,$$

because $u$ is a unit. Hence $\sigma_2(u) = \pm u^{-1}$ and it follows that $\ln|\sigma_2(u)| = \ln u^{-1} = -\ln u$. Therefore again we have

$$M = \begin{pmatrix} \ln u & -\ln u \\ 1 & 1 \end{pmatrix},$$

therefore $\det M = 2\ln u$ and so $\text{reg}(O_K) = \ln u$.

The roots of unity are $\pm 1$, so $w = 2$, therefore in both cases we have

$$k = \frac{2^2 \ln u}{2\sqrt{|\text{disc}(O_K)|}} = \frac{2 \ln u}{\sqrt{|\text{disc}(O_K)|}}.$$ 

As a fundamental unit and the discriminant $\text{disc}(O_K)$ can be determined without difficulty, we may easily find $k$. 

300
20.6 Dedekind’s ζ function

In this section we introduce the Dedekind ζ function, which generalizes the Riemann ζ function.

We consider the Dirichlet series

$$S(s) = \sum_{n \geq 1} \frac{a_n}{n^s},$$

where the $a_n$ are fixed complex numbers and $s$ a complex variable. As usual $n^s = e^{s \ln n}$. Then we have

**Lemma 20.5** If $\sum_{n \leq x} a_n$ is $O(t')$, for some $r \geq 0$, then the series $S(s)$ converges for all $s = x + iy$, with $x > r$, and is analytic in the half-plane $H_r = \{s = x + iy : x > r\}$.

**Proof** It is sufficient to show that $S(s)$ converges uniformly on every compact subset of $H_r$.

For each $s \in H_r$ we estimate the sum $\sum_{n=m}^{M} \frac{a_n}{n^s}$. Setting $A_k = \sum_{n=1}^{k} a_n$, we have

$$\sum_{n=m}^{M} \frac{a_n}{n^s} = \frac{A_n - A_{n-1}}{n^s} = \frac{A_n - A_{n-1}}{n^s} - \frac{A_{m-1}}{m^s} + \sum_{n=m}^{M-1} A_n \left( \frac{1}{n^s} - \frac{1}{(n+1)^s} \right).$$

From the $O(t')$ condition there exists a constant $C$ such that $|A_n| \leq C n^r$, for all $n$. Hence

$$\left| \sum_{n=m}^{M} \frac{a_n}{n^s} \right| \leq C \left( \frac{M^r}{M^s} + \frac{(m-1)^r}{m^s} + \sum_{n=m}^{M-1} n^r \left| \frac{1}{n^s} - \frac{1}{(n+1)^s} \right| \right).$$

Now

$$\frac{1}{n^s} - \frac{1}{(n+1)^s} = s \int_n^{n+1} \frac{dt}{t^{s+1}},$$

hence

$$\left| \frac{1}{n^s} - \frac{1}{(n+1)^s} \right| = \left| s \int_n^{n+1} \frac{dt}{t^{s+1}} \right| = \left| s \int_n^{n+1} \frac{dt}{t^{s+1}} \right| \leq \frac{|s|}{n^{s+1}}$$

and

$$\left| \sum_{n=m}^{M} \frac{a_n}{n^s} \right| \leq C \left( M^{r-x} + m^{r-x} + |s| \sum_{n=m}^{M-1} n^{r-x-1} \right).$$

We also notice that

$$\sum_{n=m}^{M-1} n^{r-x-1} \leq \int_{m-1}^{\infty} t^{r-x-1} dt = \frac{(m-1)^{r-x}}{x-r},$$

for any $m > 1$. Therefore, letting $m$ and $M$ go to infinity, we find that the sum $\sum_{n=m}^{M} \frac{a_n}{n^s}$ converges to 0, for any $s \in H_r$, and it follows that the series $S(s)$ is convergent.

If $A$ is a compact subset of $H_r$, then there is a constant $C'$ such $|s| \leq C'$, for $s \in A$. Hence, for $s \in A$, we have

$$\left| \sum_{n=m}^{\infty} \frac{a_n}{n^s} \right| \leq C \left( m^{-\epsilon} + C' \frac{(m-1)^{-\epsilon}}{\epsilon} \right).$$
We set
\[ f_m(s) = \sum_{n=1}^{m} \frac{a_n}{n^s} \quad \text{and} \quad f(s) = \sum_{n=1}^{\infty} \frac{a_n}{n^s}. \]
The functions \( f_m \) are analytic and from what we have just seen they converge uniformly to \( f \) on \( A \). It follows that \( f \) is analytic on \( H_r \).

If we set \( a_n = 1 \), for all \( n \), then \( \sum_{n \leq t} a_n = \lfloor t \rfloor \). Thus \( \sum_{n \leq t} a_n \) is \( O(t^1) \). From Lemma 20.5 the series \( S(s) \) converges for all \( s \) in the half-plane \( H_1 \) and the function
\[ \zeta(s) = \sum_{n=1}^{\infty} \frac{1}{n^s} \]
is analytic on this half-plane. This is the Riemann \( \zeta \) function.

Suppose now that \( K \) is a number field with number ring \( O_K \). From Theorem 13.5, there is a finite number of ideals with a given norm, and a countable union of finite sets is countable, so the set of ideals in \( O_K \) is countable. If we let \( j_n \) be the number of ideals \( I \) in \( O_K \) with \( \|I\| = n \), then from the ideal counting equation (20.2), we see that \( \sum_{n \leq t} j_n \) is \( O(t) \), so the series \( S(s) \) in this case also is convergent and the function
\[ \zeta_K(s) = \sum_{n=1}^{\infty} \frac{j_n}{n^s} \]
is analytic on the half-plane \( H_1 \). The function \( \zeta_K \) is referred to as the Dedekind \( \zeta \) function of the number field \( K \).

Since the ideals in \( O_K \) form a countable set, we may index them by numbers in \( \mathbb{N}^* \). Let us fix such an indexation. Then we may write
\[ \zeta_K(s) = \sum_{m=1}^{\infty} \frac{1}{\|I_m\|^s}. \]
Indeed, the series \( \sum_{m=1}^{\infty} \frac{1}{\|I_m\|^s} \) is absolutely convergent for \( s \in H_1 \): If \( s = x + iy \), then \( |\frac{1}{\|I_m\|^x}| = \frac{1}{\|I_m\|^x} \), and so \( \sum_{m=1}^{\infty} |\frac{1}{\|I_m\|^x}| = \sum_{m=1}^{\infty} \frac{1}{\|I_m\|^x} \), which is convergent for \( x > 1 \). This implies that we may rearrange the terms of series as we like, always obtaining a convergent series with the same sum. We may also introduce parentheses where we like. With an appropriate rearrangement and using parentheses, we obtain the expression defining \( \zeta_K(s) \).

**Example** At the beginning of this section we stated that the Dedekind \( \zeta \) function generalizes the Riemann \( \zeta \) function. If \( K = \mathbb{Q} \), then \( O_K = \mathbb{Z} \). The ring \( \mathbb{Z} \) is a PID and the nonzero ideals have the form \( I = (k) \), with \( k \in \mathbb{N}^* \). The cosets of \( (k) \) are \( (k), 1 + (k), \ldots, k - 1 + (k) \), so \( \|(k)\| = k \). It follows that for every \( k \in \mathbb{N}^* \) there is a unique ideal \( I \) with norm \( k \). Thus \( \zeta_{\mathbb{Q}} = \zeta \).

We aim to extend \( \zeta_K \) to a meromorphic function on the half-plane \( H_{1-[K:Q]^1} \), having a unique simple pole. We first extend \( \zeta \) to a meromorphic function on \( H_0 \). Let
\[ S_0(s) = 1 - \frac{1}{2^s} + \frac{1}{3^s} - \frac{1}{4^s} + \cdots \]
Then \( |\sum_{n \leq t} a_n| \leq 1 = t^0 \), so, from Lemma 20.5, the series converges for all \( s \in H_0 \) and the function \( S_0 \) is analytic on \( H_0 \). Again using Lemma 20.5, we obtain the absolute convergence of \( S_0 \), for \( s \in H_1 \). We claim that, for \( s \in H_1 \),

\[
S_0(s) = (1 - 2^{1-s}) \zeta(s).
\]

We show that we have the same terms in the two expressions and so, by the absolute convergence of \( S_0 \), we have equality. Indeed,

\[
\zeta(s) = S_0(s) + \frac{2}{2^s} + \frac{2}{4^s} + \frac{2}{6^s} + \cdots = S_0(s) + \frac{2^{1-s}}{1^s} + \frac{2^{1-s}}{2^s} + \frac{2^{1-s}}{3^s} + \cdots = S_0(s) + 2^{1-s} \zeta(s),
\]

thus the two expressions \( S_0(s) \) and \( (1 - 2^{1-s}) \zeta(s) \) have the same terms, hence the claim. It follows that

\[
\frac{S_0(s)}{1 - 2^{1-s}} = \zeta(s),
\]

and we may extend \( \zeta \) to a meromorphic function on the half-plane \( H_0 \), which has possible poles at points where \( 2^{1-s} = 1 \), i.e., \( s = 1 + \frac{2k\pi i}{\ln 2} \), with \( k \in \mathbb{Z} \). We set \( s_k = 1 + \frac{2k\pi i}{\ln 2} \). We claim that the only pole is at \( s_0 = 1 \). For \( s_0 = 1 \) we have

\[
S_0(1) = 1 - \frac{1}{2} + \frac{1}{3} - \frac{1}{4} + \cdots = \ln 2 \neq 0,
\]

so \( s_0 \) is a pole. This pole is in fact simple, because \( h(s) = 1 - 2^{1-s} \) has a simple root at \( s_0 \). (\( h'(s) = -\ln 2 \cdot 2^{1-s} \Rightarrow h'(1) = -\ln 2 \neq 0 \).)

We now consider \( s_k \), where \( k \neq 0 \). Let us look at the series

\[
S_1(s) = 1 + \frac{1}{2^s} - \frac{2}{3^s} + \frac{1}{4^s} + \frac{1}{5^s} - \frac{2}{6^s} + \cdots
\]

Then \( |\sum_{n \leq t} a_n| \leq 2 = 2(t^0) \), so from Lemma 20.5, the series converges for all \( s \in H_0 \) and the function \( S_1 \) is analytic on \( H_0 \). A calculation similar to that for \( S_0(s) \) shows that

\[
S_1(s) = (1 - 3^{1-s}) \zeta(s),
\]

and so

\[
\frac{S_1(s)}{1 - 3^{1-s}} = \zeta(s),
\]

for \( s \in H_1 \), and we have a second possible extension of \( \zeta \) to \( H_0 \), with possible poles at points where \( 3^{1-s} = 1 \), i.e., \( s = 1 + \frac{2k\pi i}{\ln 3} \), with \( k' \in \mathbb{Z} \). We set \( s_{k'} = 1 + \frac{2k'\pi i}{\ln 3} \). The points \( s_k \) and \( s_{k'} \) are situated on the straight line \( x = 1 \). In the former case the \( y \)-coordinate is the element \( \frac{2\pi}{\ln 2} \) multiplied by an integer and in the latter case the \( y \)-coordinate is the element \( \frac{2\pi}{\ln 3} \) multiplied by an integer. In fact, the points \( s_k \) and \( s_{k'} \) are distinct, when either \( k \) or \( k' \) is nonzero. Without loss of generality, suppose that \( k' \neq 0 \). Then

\[
s_k = s_{k'} \Rightarrow k\left(\frac{2\pi}{\ln 2}\right) = k'\left(\frac{2\pi}{\ln 3}\right) \Rightarrow k = \frac{2\ln 2}{\ln 3},
\]

which is impossible, because \( \frac{k}{k'} \) is rational and \( \frac{2\ln 2}{\ln 3} \) irrational.

For any \( k \neq 0 \), if \( s \in H_1 \), with \( s \neq s_k \), then

\[
\frac{S_0(s)}{1 - 2^{1-s}} = \zeta(s) = \frac{S_1(s)}{1 - 3^{1-s}}.
\]

303
This implies that the limit of \( \frac{S_n(s)}{1-2^{-sn}} \) as \( s \) converges to \( s_k \) from the right is finite. Consequently \( s_k \) cannot be a pole of \( \frac{S_n(s)}{1-2^{-sn}} \). Also, we have seen that 1 is a simple pole of this expression. In the following we will refer to the extension \( \frac{S_n(s)}{1-2^{-sn}} \) as the extension of \( \zeta \) to \( H_0 \). This extension is meromorphic on \( H_0 \) and has a unique pole at 1, which is simple.

We now extend \( \zeta_K \). We have

\[
\zeta_K(s) = \sum_{n=1}^{\infty} j_n n^{-s} = \sum_{n=1}^{\infty} \frac{j_n - h_K k}{n^s} + h_K k \zeta(s),
\]

where \( h_K \) is the number of ideal classes in \( O_K \) and \( k \) the constant in the ideal counting equation. The Dirichlet series with coefficients \( \frac{j_n - h_K k}{n} \) converges on the half-plane \( H_r \), with \( r = 1 - [K : \mathbb{Q}]^{-1} \), because

\[
\sum_{n \leq t} (j_n - h_K k) = O(t^{1 - \frac{1}{2}}) = O(t^r),
\]

from the ideal counting equation. This combined with the meromorphic extension of \( \zeta \) gives us a meromorphic extension of \( \zeta_K \) defined on \( H_r \), with \( r = 1 - [K : \mathbb{Q}]^{-1} \), which has a unique pole at \( s = 1 \). Moreover, this pole is simple.

### 20.7 The product form of the Dedekind \( \zeta \) function

As the set of prime ideals in \( O_K \) is a subset of the set of ideals, this set is countable, so we may index the prime ideals in \( O_K \) by numbers in \( \mathbb{N}^* \). In this section we aim to show that, for \( s \in H_1 \), we may write \( \zeta_K(s) \) in a particular product form, namely

\[
\zeta_K(s) = \prod_{n \geq 1} \left( 1 - \frac{1}{\|P_n\|^s} \right)^{-1},
\]

where \( \{P_n\}_{n \geq 1} \) is the set of prime ideals in \( O_K \).

To begin with, we will show that the given product is convergent. (For the reader not familiar with infinite products, we have included an appendix on the subject.) We fix \( s = x + iy \in H_1 \). Now,

\[
\sum_{n \geq 1} \left| \frac{1}{\|P_n\|^s} \right| = \sum_{n \geq 1} \frac{1}{\|P_n\|^s} < \sum_{m \geq 1} \frac{1}{\|I_m\|^s},
\]

which is convergent, because \( s \in H_1 \). It follows that \( \sum_{n \geq 1} \frac{1}{\|P_n\|^s} \) is absolutely convergent. To simplify the notation we will write \( a_n \) for \( \frac{1}{\|P_n\|^s} \); then \( \sum_{n \geq 1} a_n \) is absolutely convergent, which implies that \( \sum_{n \geq 1} (-a_n) \) is absolutely convergent. From Lemma 1.2 we deduce that \( \prod_{n \geq 1} (1-a_n) \) is absolutely convergent. Now, applying Theorem 1.1, we obtain that the product \( \prod_{n \geq 1} (1-a_n) \) converges to a nonzero number \( \gamma \), which is independent of the indexation of the prime ideals. It follows that \( \prod_{n \geq 1} (1-a_n)^{-1} \) converges to \( \gamma^{-1} \), independently of the arrangement of the prime ideals, so we may affirm without ambiguity that \( \prod_{n \geq 1} (1-a_n)^{-1} \) is convergent. Therefore we may write

\[
\prod_{P \in \text{Spec}(O_K), P \neq (0)} \left( 1 - \frac{1}{\|P\|^s} \right)^{-1}
\]
for this product. We aim to show that the product has the value \( \zeta_K(s) \), for \( s \in H_1 \). First we notice that
\[
(1 - a_n)^{-1} = 1 + a_n + a_n^2 + \cdots,
\]
hence
\[
(1 - a_1)^{-1}(1 - a_2)^{-1} = 1 + (a_1 + a_2) + (a_1^2 + a_1 a_2 + a_2^2) + \cdots = 1 + \sum a_1^{r_1} a_2^{r_2},
\]
where \( r_1 \) and \( r_2 \) range over \( \mathbb{N} \) and are not simultaneously 0. Now, using the multiplicativity of the norm of an ideal (Theorem 13.2), we have
\[
a_1^{r_1} a_2^{r_2} = \frac{1}{\|P_1\|^{r_1 s} \|P_2\|^{r_2 s}} = \frac{1}{\|P_1^{r_1} P_2^{r_2}\|^s}.
\]
For distinct values of \( r_1 \) and \( r_2 \), the ideals \( P_1^{r_1} P_2^{r_2} \) are distinct, so the expression \( \sum a_1^{r_1} a_2^{r_2} \) is just the sum of the values of \( \frac{1}{\|\|} \), where the sum is taken over all ideals whose decomposition is a product of powers of the ideals \( P_1 \) and \( P_2 \). We set \( A_2 = 1 + \sum a_1^{r_1} a_2^{r_2} \).

In the same way, for the product of \( (1 - a_1)^{-1}, (1 - a_2)^{-1} \) and \( (1 - a_3)^{-1} \), we obtain
\[
(1 - a_1)^{-1}(1 - a_2)^{-1}(1 - a_3)^{-1} = 1 + \sum a_1^{r_1} a_2^{r_2} a_3^{r_3},
\]
where \( r_1, r_2 \) and \( r_3 \) range over \( \mathbb{N} \) and are not simultaneously 0. The expression \( \sum a_1^{r_1} a_2^{r_2} a_3^{r_3} \) is just the sum of the values of \( \frac{1}{\|\|} \), where the sum is taken over all ideals whose decomposition is a product of powers of the ideals \( P_1, P_2 \) and \( P_3 \). Let us set \( A_3 = 1 + \sum a_1^{r_1} a_2^{r_2} a_3^{r_3} \).

Continuing in the same way, for any \( n \in \mathbb{N}^* \) we obtain
\[
(1 - a_1)^{-1}\cdots(1 - a_n)^{-1} = 1 + \sum a_1^{r_1}\cdots a_n^{r_n},
\]
where \( r_1, \ldots r_n \) range over \( \mathbb{N} \) and are not simultaneously 0. The expression \( \sum a_1^{r_1}\cdots a_n^{r_n} \) is the sum of the values of \( \frac{1}{\|\|} \), where the sum is taken over all ideals whose decomposition is a product of powers of the ideals \( P_1, \ldots, P_n \). We set \( A_0 = 1 \), and for \( n \geq 1 \), \( A_n = 1 + \sum a_1^{r_1}\cdots a_n^{r_n} \).

We are now in a position to prove the result referred to above.

**Theorem 20.2** If \( s \in H_1 \), then
\[
\zeta_K(s) = \prod_{P \in \text{Spec}(O_K), P \neq (0)} \left( 1 - \frac{1}{\|P\|^s} \right)^{-1},
\]
where \( \text{Spec}(O_K) \) denotes the collection of prime ideals in \( O_K \).

**Proof** As the series \( \zeta_K(s) = \sum_{m=1}^{\infty} \frac{1}{\|\|^s} \), with \( s \in H_1 \), is absolutely convergent, any rearrangement of the terms gives us another series converging to \( \zeta_K(s) \). We now construct a useful rearrangement.

Let \( T_0 \) be composed of the single ideal \( O_K \). We give \( O_K \) some index, say 0. Every nontrivial ideal \( I \) in \( O_K \) which is not equal to \( O_K \) can be written in a unique way as a product of prime ideals: \( I = P_1^{r_1} \cdots P_n^{r_n} \), where at least one \( r_i \) is nonzero. We index the ideals in \( O_K \) in the

\[
305
\]
following way: First we index the set $T_1$ composed of the powers of $P_1$ with indices not equal to 0. (We could use the powers of $P_1$ as indices.)

Next we consider the set $T_2$ composed of products of $P_1$ and $P_2$, which do not belong to $T_0 \cup T_1$. We index these elements with indices which we have not already used.

Now we consider the set $T_3$ composed of products of powers of $P_1$, $P_2$ and $P_3$, which do not belong to $T_0 \cup T_1 \cup T_2$. We index the elements of $T_3$ once again with indices which we have not previously used.

Continuing in the same way we obtain an indexation of all nontrivial ideals. From this indexation we obtain a rearrangement of the terms in the series for $\zeta_K(s)$.

We recall that

$$\zeta_K(s) = \sum_{n=1}^{\infty} \frac{1}{\|I_n\|^s},$$

where the $I_m$ are the ideals in $O_K$, indexed in some arbitrary way. As the series is absolutely convergent, we may group the terms into ‘packets’, choosing a permutation allowing us to sum the ‘packets’ in the order we desire. Thus

$$\zeta_K(s) = \sum_{n \geq 0} \left( \sum_{I \in T_n} \frac{1}{\|I\|^s} \right).$$

If

$$B_n = \sum_{I \in T_0 \cup \ldots \cup T_n} \frac{1}{\|I\|^s},$$

then $\lim_{n \to \infty} B_n = \zeta_K(s)$. However, $B_n = A_n$ and $\lim_{n \to \infty} A_n = \prod_{i=1}^{\infty} \left( 1 - \frac{1}{\|P_i\|^s} \right)^{-1}$. Hence we have the equality

$$\zeta_K(s) = \prod_{P \in \text{Spec}(O_K), P \neq (0)} \left( 1 - \frac{1}{\|P\|^s} \right)^{-1},$$

as claimed. \hfill \Box

**Corollary 20.1** For $s \in H_1$, we have $\zeta_K(s) \neq 0$.

**Proof** Since the expression of $\zeta_K(s)$ as a product is nonzero, we have the result. \hfill \Box

**Remark** From what we have just seen, we may find a multiplicative expression for the Riemann $\zeta$ function. Setting $K = \mathbb{Q}$, for $s \in H_1$ we obtain

$$\zeta(s) = \zeta_{\mathbb{Q}}(s) = \prod (1 - \frac{1}{p^s})^{-1},$$

where the product is taken over all prime numbers in $\mathbb{N}^*$.

## 20.8 The class number formula

In this section we bring together the ideal counting equation and the Dedekind $\zeta$ function to obtain a relation involving the class number of a number ring. This is known as the **class number formula**. We begin with a preliminary result concerning the Riemann $\zeta$ function.
Proposition 20.2 For the Riemann $\zeta$ function, we have
\[
\lim_{s \to 1^+} (s - 1)\zeta(s) = 1.
\]

Proof We have seen that the series
\[
S_0(s) = \sum_{n=1}^{\infty} \frac{(-1)^{n-1}}{n^s},
\]
is convergent and holomorphic on the open half-plane $H_0$; also, for $s$ in the half-plane $H_1$,
\[
\zeta(s) = \frac{S_0(s)}{1 - 2^{1-s}}.
\]
As $S_0$ is continuous at 1, \(\lim_{s \to 1^+} S_0(s) = \ln 2\). On the other hand, we have
\[
2^{1-s} - 1 = (-\ln 2)2^{1-s'}(s - 1),
\]
where $s' \in (1, s)$. It follows that
\[
\frac{2^{1-s} - 1}{s - 1} = (-\ln 2)2^{1-s'} \implies \lim_{s \to 1^+} \frac{2^{1-s} - 1}{s - 1} = -\ln 2.
\]
Hence
\[
\lim_{s \to 1^+} (s - 1)\zeta(s) = 1,
\]
as required. \(\square\)

This result may be written in the form: \(\lim_{s \to 1^+} (s - 1)\zeta_K(s) = 1\). We now replace $\mathbb{Q}$ by any number field $K$ and consider the limit \(\lim_{s \to 1^+} (s - 1)\zeta_K(s)\). We set $b_l = j_l - h_K k$, where $h_K$ is the class number of $O_K$ (or of $K$) and $k$ the constant whose value is given by
\[
k = \frac{2^{r+s}\pi^s \text{reg}(O_K)}{w \sqrt{|\text{disc}(O_K)|}},
\]
where \text{reg}(O_K) is the regulator of $O_K$ as defined above, $r$ (resp. $s$) the number of real (resp. complex) embeddings of $K$ in $\mathbb{C}$ and $w$ the number of roots of unity in $O_K$. We have seen above that the Dirichlet series $S_2(s)$ with coefficients $\frac{h}{s}$ converges and is analytic on the half-plane $H_r$, with $r = 1 - [K : \mathbb{Q}]^{-1}$. In particular, $S_2(1)$ is finite. Now,
\[
S_2(s) = \zeta_K(s) - h_K k\zeta(s) \implies \lim_{s \to 1^+} (s - 1)S_2(s) = \lim_{s \to 1^+} (s - 1)\zeta_K(s) - h_K k \lim_{s \to 1^+} (s - 1)\zeta(s)
\]
and, from Proposition 20.2, it follows that
\[
\lim_{s \to 1^+} (s - 1)\zeta_K(s) = \frac{2^{r+s}\pi^s \text{reg}(O_K)}{w \sqrt{|\text{disc}(O_K)|}} h_K.
\]
This expression is referred to the class number formula.

Remark It should be noticed that in general the class number $h_K$ is difficult to determine, hence the expression \(\lim_{s \to 1^+} (s - 1)\zeta_K(s)\) is difficult to evaluate from the formula. On the other hand, using the formula to calculate the class number is also difficult, because the expression \(\lim_{s \to 1^+} (s - 1)\zeta_K(s)\) is not easy to determine directly.
Appendix A

Formal power series, polynomials and polynomial functions

In this appendix we summarize the main results on polynomials which we use in the text. We make a clear distinction between polynomials and polynomial functions, something which is often neglected. Also, we present polynomials in the context of formal power series, which seems to us quite natural. We do not give any proofs. These can be found elsewhere in standard algebra texts, for example [1] or [14].

Formal power series

Let $R$ be a commutative ring with identity. A sequence $A = (a_i)_{i=0}^\infty$ of elements of $R$ is called a formal power series over $R$. We will write $S_R$ for the set of all such power series. We define an addition $\oplus$ pointwise on $S_R$: If $A = (a_i)$ and $B = (b_i)$, then we set $A \oplus B = (a_i + b_i)$. With this operation $S_R$ is a group, with identity $O = (o_i)$, where $o_i = 0$ for all $i$. The inverse of $A = (a_i)$ is $-A = (-a_i)$.

We also define a multiplication $\odot$ on $S_R$: for $A,B \in S_R$, we set $C = (c_i) \in S_R$, where $c_i = \sum_{k+l=i} a_kb_l$. We write $C = A \odot B$. With this operation and the addition, $S_R$ is a ring with identity $U = (u_i)$, where $u_0 = 1$ and $u_i = 0$ for $i \neq 0$. An element $A$ is invertible (for the multiplication) if and only if $a_0$ is invertible in $R$. An element $X \in S_R$ plays a special role. We define $X = (x_i)$ by $x_1 = 1$ and $x_i = 0$ for $i \neq 1$. Then it easy to check that, if $X^k = (y_i)$, then $y_k = 1$ and $y_i = 0$ for $i \neq k$. If we set $X^0 = U$, then we can write the power series $A = \sum_{i=0}^\infty a_i \cdot X^i$. By convention we usually write $R[[X]]$ for $S_R$ and call the ring we have just defined the ring of formal power series over $R$.

We also define a scalar multiplication $\cdot$ on $S_R$: for $\lambda \in R$, $\lambda \cdot (a_i) = (\lambda a_i)$. With the addition, $S_R$ is an $R$-module (an $R$-vector space, if $R$ is a field) and with the three operations an algebra.

We make certain simplifications in the notation: we write $A + B$ for $A \oplus B$, $AB$ for $A \odot B$ and $\lambda A$ for $\lambda \cdot A$.

Polynomials

It may be so that a power series has only a finite number of nonzero coordinates. We call
such power series polynomials over $R$. We note the set of polynomials $R[[X]]$, which is a subring of $R[[X]]$, when $R[[X]]$ is considered as a ring, and a submodule (resp. vector subspace), when $R[[X]]$ is considered as an $R$-module (resp. $R$-vector space).

If $A \in R[X]$ and $A \neq O$, then we define the degree of $A$, written $\deg A$, to be $\max\{i : a_i \neq 0\}$. The coefficient $a_i$, where $i = \deg A$ is called the leading coefficient of $A$. If the leading coefficient has the value 1, then we say that the polynomial is monic. We define the degree of the zero polynomial $O$ to be $-\infty$. If $A = (a_i)$ is a nonzero polynomial and $\deg A = n$, then we may write $A = \sum_{i=0}^n a_i X^i$. The degree has the following properties:

- $\deg(-A) = \deg A$;
- $\deg(A + B) \leq \max\{\deg A, \deg B\}$;
- $\deg AB = \deg A + \deg B$, if $R$ is an integral domain.

From the third property we easily derive that, if $R$ is an integral domain, then $R[X]$ is an integral domain and the set of invertible elements $R[X]^\times$ is composed of the constant polynomials $A = a$, where $a \in R^\times$.

We may consider division of one polynomial by another. We have the following result:

**Theorem A.1** Let $B$ be a nonzero polynomial in $R[X]$, with leading coefficient invertible in $R$. For any $A \in R[X]$, there exist unique polynomials $Q, S \in R[X]$ such that

$$A = QB + S,$$

where $\deg S < \deg B$.

The polynomial $Q$ (resp. $R$) is called the quotient (resp. remainder) of $A$ divided by $B$. Clearly, if $R$ is a field, then the polynomial $B$ can be any nonzero polynomial. The polynomial $B$ divides $A$ if and only if $S = O$.

**Polynomial functions**

For a commutative ring $R$ with identity, we note $\mathcal{F}(R)$ the collection of functions from $R$ into itself. We define three operations on $\mathcal{F}(R)$:

$$f \oplus g)(x) = f(x) + g(x) \quad (f \odot g)(x) = f(x)g(x) \quad (z \cdot f)(x) = zf(x),$$

for all $x, z \in R$ and $f, g \in \mathcal{F}(R)$. With the first two operations $\mathcal{F}(R)$ is a ring with identity, and with the first and third operations $\mathcal{F}(R)$ is an $R$-module. We may define a mapping

$$\Phi : R[X] \longrightarrow \mathcal{F}(R), A \longmapsto \bar{A}$$

in the following way. Let $x \in R$ and $A \in R[X]$. If $A \neq O$ and $A = \sum_{i=0}^n a_i X^i$, then we set $\bar{A}(x) = \sum_{i=0}^n a_i x^i$ and if $A = O$, then we set $\bar{O}(x) = 0$. The mapping $\Phi$ is a ring homomorphism and also an $R$-module homomorphism. The image of $\Phi$, which we will write $\mathcal{P}(R)$, is a subring of $\mathcal{F}(R)$ and also an $R$-submodule. The image $\bar{A}$ of $A$ is called the polynomial function associated to $A$. We should notice that there is a clear distinction between polynomials and polynomial functions. When there is no confusion possible, we often write $A$ for $\bar{A}$.

If $\alpha \in R$ and $\bar{A}(\alpha) = 0$, then we say that $\alpha$ is a root of $A$. The following result is fundamental. It is an easy consequence of Theorem A.1.
Proposition A.1 Let $A \in R[X]$. Then $\alpha \in R$ is a root of $A$ if and only if $-\alpha + X$ divides $A$.

It may be so that a power of $-\alpha + X$ greater than 1 divides $A$. If $(-\alpha + X)^k$ divides $A$, but $(-\alpha + X)^{k+1}$ does not, then we say that the root $\alpha$ has multiplicity $k$. We will write $\nu(\alpha)$ for the multiplicity of the root $\alpha$. Roots with multiplicity 1 are said to be simple; on the other hand, roots with multiplicity $k > 1$ are called multiple roots. We must be careful with the number of roots: in general, this number is bounded, however there are polynomials with an infinite number of roots. In the case where $A$ is an integral domain we have the following important result.

Theorem A.2 Let $R$ be an integral domain and $A$ a nonzero polynomial in $R[X]$. Then the number of roots of $A$, counted with multiplicity, is bounded by the degree of $A$. If $R$ is an algebraically closed field, then we have equality.

Remark If $R$ is not an integral domain, then Theorem A.2 may not be true. For example, if $f \in \mathbb{Z}_8[X]$, with $f(X) = 4X$, then $\deg f = 1$, but $f$ has four roots, namely 0, 2, 4, 6.

Differentiation of polynomials

Let $A \in R[X]$ of degree $n$. We define the derivative $A' \in R[X]$ of $A$ in the following way. If $\deg A \leq 0$, i.e., if $A$ is a constant polynomial, then $A = O$; if $\deg A \geq 1$ and $A = \sum_{i=0}^{n} a_i X^i$, then

$$A' = \sum_{i=1}^{n} i a_i X^{i-1} = \sum_{i=0}^{n-1} (i+1) a_{i+1} X^i.$$  

Clearly $\deg A' \leq \deg A - 1$; however, the inequality may be strict. The following result is not difficult to prove.

Theorem A.3 If $A, B \in R[X]$ and $z \in R$, then

- $(A + B)' = A' + B'$;
- $(zA)' = zA'$;
- $(AB)' = AB' + A'B$.

Corollary A.1 The mapping $D : R[X] \to R[X], A \mapsto A'$ is a an $R$-module homomorphism.

The derivative is useful in finding multiple roots:

Proposition A.2 If $\alpha \in R$ and $A \in R[X]$, then $\alpha$ is a multiple root of $A$ if and only if $\alpha$ is a root of both $A$ and $A'$. 
Remark We may extend the notion of root in the following way. If \( R \) is an integral domain and \( A \in R[X] \), then any \( \alpha \) in an extension of the field of fractions of \( R \) is called a root of \( A \) if \( A(\alpha) = 0 \).

Irreducible polynomials

We recall that an element \( a \) in a ring \( R \) is irreducible if it is neither 0 nor invertible and, if there are elements \( b, c \in R \) such that \( a = bc \), then either \( b \) or \( c \) is invertible. Also, two elements \( a \) and \( b \) are associates, if there exists an invertible element \( c \) such that \( a = cb \). If \( R \) is an integral domain and every element \( a \in R \), which is neither 0 nor invertible can be written as a product of a unit and irreducible elements and, given two complete factorizations of \( a \)

\[
a = ub_1 \cdots b_r = vc_1 \cdots c_s,
\]

where \( u \) and \( v \) are units and the \( b_i \) and \( c_j \) are irreducible, then we have \( r=s \) and the \( b_i \) can be renumbered so that each \( c_j \) is associated to \( b_j \), then we say that \( R \) is a unique factorization domain (UFD). A basic property of UFDs is that any two elements \( a \) and \( b \) have a highest common factor (HCF) \( d \) and a lowest common multiple (LCM) \( m \). In addition, \( dm \) is an associate of \( ab \) (see [5]).

If \( R \) is a unique factorization domain and \( A \in R[X] \), with \( A \neq 0 \), then the content of \( A \), which we write \( c(A) \), is the HCF of the coefficients of \( A \). We say that a polynomial is primitive if its content is 1. Clearly, we may write \( A = c(A)B \), where \( c(B) = 1 \). The following result is known as Gauss’s lemma.

**Theorem A.4** If \( R \) is a UFD and \( A, B \in R[X] \) are nonzero, then \( c(AB) = c(A)c(B) \), up to association. Thus the product of two primitive polynomials is primitive.

This apparently simple result enables us to prove several other important results. Proofs may be found, for example, in [1].

**Theorem A.5** Let \( R \) be a unique factorization domain, with quotient field \( F \), and \( A \in R[X] \). Then, if \( A \) is nonconstant and irreducible in \( R[X] \), then \( A \) is irreducible in \( F[X] \). On the other hand, if \( A \) is primitive and irreducible in \( F[X] \), then \( A \) is irreducible in \( R[X] \).

**Theorem A.6** If \( R \) is a UFD, then so is \( R[X] \).

**Theorem A.7** (Eisenstein’s irreducibility criterion) Let \( R \) be a UFD, with quotient field \( F \), and \( A \in R[X] \), with \( \deg A = n \geq 1 \). If there is an irreducible element \( p \in R \) such that \( p \) divides \( a_i \) for \( i = 0, \ldots, n-1 \), \( p \) does not divide \( a_n \), and \( p^2 \) does not divide \( a_0 \), then \( A \) is irreducible in \( F[X] \). If, in addition, \( A \) is primitive, then \( A \) is irreducible in \( R[X] \).

Multivariate polynomials

We may define polynomials in an alternative way. We let \( X \) be a symbol and define \( \tilde{R}[X] \) to be the collection of expressions of the form

\[
A = \sum_{i=0}^{m} a_i X^i,
\]

where the \( a_i \in R \), \( m \in \mathbb{N} \), \( X^0 = 1 \). We call the terms \( a_i X^i \) monomials. For \( A, B \in \tilde{R}[X] \), we define their sum \( A \oplus B \) by adding the coefficients of terms having the same power of \( X \). If
A = aX^i and B = bX^j, then we define A \odot B = abX^{i+j}. We may extend this multiplication: if 
A = \sum_{i=0}^{m} a_iX^i and B = \sum_{j=0}^{n} a_jX^j, then we multiply pairs of elements (aX^i, bX^j) and then 
add resulting monomials having the same power; this gives us A \odot B. Finally, we define a scalar 
multiplication: if \( \lambda \in R \) and \( A = \sum_{i=0}^{m} a_iX^i \) then we set \( \lambda \cdot A = \sum_{i=0}^{m} \lambda a_iX^i \). With the three 
operations so defined \( \tilde{R}[X] \) is an \( R \)-algebra isomorphic to \( R[X] \). As above, we write \( A + B \) for 
\( A \odot B, AB \) for \( A \odot B \) and \( \lambda A \) for \( \lambda \cdot A \) and we identify \( R[X] \) and \( \tilde{R}[X] \).

The alternative way of defining polynomials enables us to extend the definition to polynomials 
in several variables over a commutative ring \( R \) with identity. We let \( X_1, \ldots, X_n \) be \( n \) commuting 
symbols, often referred to as variables or indeterminates, and we define \( \tilde{R}[X_1, \ldots, X_n] \) to be the 
collection of expressions of the form

\[ A = \sum_{s_1, \ldots, s_n} a_{s_1, \ldots, s_n} X_1^{s_1} \cdots X_n^{s_n}, \]

where \( a_{s_1, \ldots, s_n} \in R \) and the sum is finite. Each term \( a_{s_1, \ldots, s_n} X_1^{s_1} \cdots X_n^{s_n} \) is said to be a monomial. 
We call the elements of \( \tilde{R}[X_1, \ldots, X_n] \) polynomials in \( n \) variables or indeterminates. We define 
an addition \( \oplus \) on elements of \( \tilde{R}[X_1, \ldots, X_n] \) by adding like monomials in the expressions of 
polynomials and scalar multiplication \( \cdot \) by an element \( \lambda \in R \) by multiplying the coefficients of all 
the monomials by \( \lambda \). We define a multiplication \( \odot \) first on monomials. If \( A = aX_1^{s_1} \cdots X_n^{s_n} \) and 
\( B = bX_1^{t_1} \cdots X_n^{t_n} \), then we set \( A \odot B = abX_1^{s_1+t_1} \cdots X_n^{s_n+t_n} \). We extend this multiplication to 
any pair of polynomials \( A \) and \( B \) by first multiplying all pairs of monomials \( m_A, m_B \), with \( m_A \) 
a monomial of \( A \) and \( m_B \) a monomial of \( B \), and then adding the monomials obtained with 
the same powers of each \( X_i \). With the three operations so defined \( \tilde{R}[X_1, \ldots, X_n] \) is an \( R \)-algebra. 
As above, we write \( A + B \) for \( A \odot B, AB \) for \( A \odot B \) and \( \lambda A \) for \( \lambda \cdot A \). We call the maximum 
value of \( s_1 + \cdots + s_n \) the total degree of the polynomial \( A \), which we note \( \deg A \).

**Exercise A.1** Show that \( \tilde{R}[X_1, \ldots, X_n] \) is an integral domain if and only if \( R \) is an integral 
domain.

If \( F \) is a field and \( f \in F[X] \) has an infinite number of roots, then \( f \) is the zero polynomial. The 
situation with multivariate polynomials is not the same. For example, if \( f(X, Y) = -X + Y^2 \in 
\tilde{R}[X, Y] \), then \( f \) has an infinite number of roots, but \( f \) is not the zero polynomial. However, if 
the infinite set on which \( f \) vanishes has a certain form, then we can assert that \( f \) is the zero 
polynomial.

**Theorem A.8** Let \( F \) be a field and \( A_1, \ldots, A_n \) infinite subsets of \( F \). If \( f \in F[X_1, \ldots, X_n] \) 
vanishes on the cartesian product \( A_1 \times \cdots \times A_n \), then \( f \) is the zero polynomial.

**Proof** We use an induction on \( n \), the number of indeterminates. If \( n = 1 \), then there is nothing 
to prove. Suppose now that \( n > 1 \) and the result is true up to \( n-1 \). Let \( f \in F[X_1, \ldots, X_n] \) and 
\( A_1, \ldots, A_n \) infinite subsets of \( F \) such that \( f \) vanishes on \( A_1 \times \cdots \times A_n \). Fixing \( a \in A_n \), we obtain 
a polynomial \( g_n(X_1, \ldots, X_{n-1}) = f(X_1, \ldots, X_{n-1}, a) \) in \( n-1 \) indeterminates. By the induction 
hypothesis, \( g_n \) has the value 0 on all members of \( F^{n-1} \). We may consider \( f \) as an element of 
\( F(X_1, \ldots, X_{n-1})[X_n] \), which has the value 0 on all values of \( A_n \). As this is a polynomial in one 
determinate, it vanishes on \( F \). We have shown that \( f \) is the zero polynomial on \( F^n \). This 
completes the induction step and hence the proof. \( \Box \)

Partial fraction decomposition

Let \( K \) be a field and \( K[X] \) the integral domain of polynomials with coefficients in \( K \). We 
note \( K(X) \) the field of fractions of \( K[X] \). The following theorem generalizes a well-known result of 
elementary analysis.

312
Theorem A.9 Let $K$ be a field and $\phi_1, \ldots, \phi_l$ distinct polynomials in $K[X]$ with positive degrees $d_1, \ldots, d_l$. We suppose that $n_1, \ldots, n_l$ are fixed positive integers and define $g = \prod_{k=1}^{l} \phi_k^{n_k}$ and set $N = \deg g$. Then the following conditions are equivalent:

- **a.** The polynomials $\phi_1, \ldots, \phi_l$ are pairwise coprime.
- **b.** For every $f \in K[X]$ with $\deg f < N$, there exist unique polynomials $\{p_{kj}\}_{1 \leq k \leq l}^{1 \leq j \leq n_k}$ in $K[X]$, with $\deg p_{kj} \leq d_k - 1$ such that $\frac{f}{g}$ may be written in the form

$$\frac{f}{g} = \sum_{k=1}^{l} \sum_{j=1}^{n_k} p_{kj} \phi_j^{d_k}.$$

- **c.** Statement b. without the uniqueness condition.

**Proof** see [2]

We refer to this result as the partial fraction decomposition theorem.
Appendix B

Symmetric polynomials

If $A$ is a polynomial in $n$ indeterminates, then we obtain another polynomial $\sigma A$ if we permute the indeterminates $X_i$ by the permutation $\sigma$: the monomial $aX_1 \cdots X_n$ becomes $aX_{\sigma(1)} \cdots X_{\sigma(n)}$. The polynomial $A \in R[X_1, \ldots, X_n]$ is symmetric if, for all permutations $\sigma \in S_n$, $\sigma A = A$. We write $R'[X_1, \ldots, X_n]^{S_n}$ for the collection of symmetric polynomials over $R$. These form a subalgebra of $R[X_1, \ldots, X_n]$.

We define the polynomials $\Sigma_1, \ldots, \Sigma_n$ as follows:

\[ \Sigma_1 = \sum_{i=1}^{n} X_i, \quad \Sigma_2 = \sum_{i<j} X_i X_j, \ldots, \Sigma_k = \sum_{1 \leq i_1 < \cdots < i_k \leq n} X_{i_1} \cdots X_{i_k}, \quad \Sigma_n = X_1 \cdots X_n. \]

These polynomials are symmetric and are called the elementary symmetric polynomials in $R'[X_1, \ldots, X_n]$. Each $\Sigma_k$ is the sum of $\binom{n}{k}$ monomials of degree $k$. We will sometimes write $\Sigma_k^{(n)}$, instead of $\Sigma_k$, to indicate the number of indeterminates. A symmetric polynomial can be expressed in terms of these polynomials, as we will soon see. First we need to generalize the notion of degree in a particular way.

We have seen the notion of total degree, which generalizes that of degree for a polynomial in one variable. However, we may generalize the notion of degree in another way. First we define an order $<$ on $\mathbb{N}^n$: if $I = (i_1, \ldots, i_n)$ and $J = (j_1, \ldots, j_n)$ and there exists $k$ such that $a_i = b_i$, for $i < k$, and $a_k < b_k$, then we write $I < J$. Clearly $<$ defines a total order on $\mathbb{N}^n$, said to be a lexicographic order. It is easy to see that, if $I, J, K \in \mathbb{N}^n$, then

\[ I < J \implies I + K < J + K. \]

We now consider a polynomial

\[ A = \sum_{i_1, \ldots, i_n} a_{i_1, \ldots, i_n} X_1^{i_1} \cdots X_n^{i_n}, \]

which we often abbreviate to $\sum_I a_I X^I$. We notice that $X^I X^J = X^{I+J}$. For a nonzero polynomial $A$ we call the multidegree of $A$

\[ \text{mdeg } A = \max\{I : a_I \neq 0\}. \]

If $\text{mdeg } A = I$, then we call $a_I X^I$ the leading term of $A$ and $a_I$ the leading coefficient of $A$, which we note lead $A$. For the elementary symmetric polynomials we have

\[ \text{mdeg } \Sigma_1 = (1, 0, \ldots, 0), \quad \text{mdeg } \Sigma_2 = (1, 1, 0, \ldots, 0), \ldots, \quad \text{mdeg } \Sigma_n = (1, 1, \ldots, 1). \]

The multidegree has properties similar to those of the degree.
Proposition B.1 If \(A, B \in R[X_1, \ldots, X_n]\) are nonzero, then

- \(\text{mdeg } AB = \text{mdeg } A + \text{mdeg } B\), if \(R\) is an integral domain;
- \(\text{mdeg } (A + B) \leq \max(\text{mdeg } a, \text{mdeg } B)\);
- \(\text{mdeg } (A + B) = \text{mdeg } B\), if \(\text{mdeg } A < \text{mdeg } B\).

Proof Let

\[
A = \sum_{I<K} a_I X^I + a_K X^K \quad \text{and} \quad B = \sum_{J<L} b_J X^J + b_L X^L.
\]

Then \(AB\) has the nonzero term \(a_K b_L X^{K+L}\) and the other terms have multidegrees strictly less than \(K + L\). Hence

\(\text{mdeg } AB = \text{mdeg } A + \text{mdeg } B\).

The multidegrees of the monomials of \(A + B\) are those of \(A\) and \(B\), with the exception of those eliminated when the coefficients of a monomial in \(A\) and a monomial in \(B\) have opposite signs. It follows that

\(\text{mdeg } (A + B) \leq \max(\text{mdeg } a, \text{mdeg } B)\).

If \(\text{mdeg } A < \text{mdeg } B\), then the leading term of \(A + B\) is that of \(B\), hence

\(\text{mdeg } (A + B) = \text{mdeg } B\).

This ends the proof. \(\square\)

We now prove a fundamental result relating symmetric and elementary symmetric polynomials.

Theorem B.1 Let \(R\) be a commutative ring with identity. If \(A \in R[X_1, \ldots, X_n]^{S_n}\), then there exists a unique polynomial \(S \in R[X_1, \ldots, X_n]\) such that

\[A = S(\Sigma_1, \ldots, \Sigma_n),\]

where \(S(\Sigma_1, \ldots, \Sigma_n)\) is the polynomial \(S\) with \(X_i\) replaced by \(\Sigma_i\).

Proof Existence If \(A\) is the zero polynomial, then there is nothing to prove, so let us suppose that this is not the case. We use an argument by induction on the multidegree. If \(\text{mdeg } A = (0, \ldots, 0)\), then \(A\) is constant and we may take \(S = A\).

Now suppose that \(\text{mdeg } A = K = (k_1, \ldots, k_n)\), with \(K \neq (0, \ldots, 0)\). We have

\[A = \sum_{I<K} a_I X^I + a_K X^K,
\]

with \(a_K \neq 0\). We claim that \(k_1 \geq k_2 \geq \cdots \geq k_n\). As \((k_1, \ldots, k_n)\) is the multidegree of a nonzero monomial in \(A\) and \(A\) is symmetric, all permutations of the \(k_i\) appear as multidegrees of monomials of \(A\) and \(K\) is greater than any of these permutations. If, for some \(i\), \(k_i < k_{i+1}\), then the sequence obtained by permutation of \(k_i\) and \(k_{i+1}\) is greater than \(K\) and so \(\text{mdeg } A \neq K\), a contradiction, thus \(k_i \geq k_{i+1}\), for all \(i\). We now set

\[a_1 = k_1 - k_2, \quad a_2 = k_2 - k_3, \ldots, a_{n-1} = k_{n-1} - k_n, \quad a_n = k_n.
\]

As \(k_i \geq k_{i+1}\), for all \(i\), the elements \(a_i\) are all positive and \(B = a_K \Sigma_1^{a_1} \cdots \Sigma_n^{a_n}\) is a polynomial. Since the elementary symmetric polynomials are monic, we have
In order to prove the uniqueness of the polynomial
we may write
\[ q(x) = a_1n \deg \Sigma_1 + a_2n \deg \Sigma_2 + \cdots + a_n \Sigma_n \]
\[ = (a_1, 0, \ldots, 0) + (a_2, a_2, 0, \ldots, 0) + \cdots (a_n, \ldots, a_n) \]
\[ = (a_1 + a_2 + \cdots + a_n, a_2 + \cdots + a_n, \ldots, a_n) \]
\[ = (k_1, k_2, \ldots, k_n) = \text{mdeg} A. \]

It follows that \( A \) and \( B \) have the same leading term, namely \( a_K X^K \). If \( A = B \), then we are
done. If this is not the case and we set \( C = A - B \), then \( \text{mdeg} C < K \). As \( C \) is symmetric, there
is a polynomial \( S' \in R[X_1, \ldots, X_n] \) such that \( C = S'[\Sigma_1, \ldots, \Sigma_n] \) and
\[ A = B + C = a_K \Sigma_1^{a_1} \cdots \Sigma_n^{a_n} + S'[\Sigma_1, \ldots, \Sigma_n] = S'[\Sigma_1, \ldots, \Sigma_n]. \]

This finishes the induction step.

Uniqueness In order to prove the uniqueness of the polynomial \( S \), we will prove, by induction
on \( n \), the number of variables, that, if \( Q \in R[X_1, \ldots, X_n] \) and \( Q[\Sigma_1, \ldots, \Sigma_n] = 0 \), then \( Q = 0 \).
First, if \( n = 1 \), then \( \Sigma_1 = X \) and the only possibility is clearly \( Q = 0 \). Suppose now that \( n \geq 2 \).
We may write
\[ Q = \sum_{k=0}^{N} Q_k X_n^k, \]
where \( Q_k \in R[X_1, \ldots, X_{n-1}] \). If \( Q \neq 0 \), then there is a \( Q_i \neq 0 \). We set \( p = \min\{i : Q_i \neq 0\} \).
Then
\[ 0 = Q(\Sigma_1, \ldots, \Sigma_n) = \sum_{k=p}^{N} Q_k (\Sigma_1, \ldots, \Sigma_{n-1}) \Sigma_n^{k-p}. \]

Using the fact that \( \Sigma_n^p \) is monic, we obtain
\[ Q_p(\Sigma_1, \ldots, \Sigma_{n-1}) + Q_{p+1}(\Sigma_1, \ldots, \Sigma_{n-1}) \Sigma_n + Q_{p+2}(\Sigma_1, \ldots, \Sigma_{n-1}) \Sigma_n^2 + \cdots = 0. \]

We define a mapping from \( R[X_1, \ldots, X_n] \) into \( R[X_1, \ldots, X_{n-1}] \) by setting \( X_n = 0 \). (We discard all monomials with a power of \( X_n \).) The mapping \( \psi \) is a surjective ring homomorphism and
\[ \text{Ker} \psi = \{ A \in R[X_1, \ldots, X_n] : A = aX^n, a \in R \}. \]

Then
\[ \psi(Q_p(\Sigma_1^{(n)}, \ldots, \Sigma_{n-1}^{(n)})) = Q_p(\Sigma_1^{(n-1)}, \ldots, \Sigma_{n-1}^{(n)}) \quad \text{and} \quad \psi(\Sigma_n^{(n)}) = 0, \]

hence
\[ Q_p(\Sigma_1^{(n-1)}, \ldots, \Sigma_{n-1}^{(n)}) = 0. \]

From the induction hypothesis, \( Q_p = 0 \), a contradiction. It follows that \( Q = 0 \), which is what
we set out to prove.

\textbf{Corollary B.1} Let \( R \) and \( S \) be commutative rings with identity such that \( R \subset S \). We suppose
that \( f \in R[X] \), with leading term invertible and roots \( \alpha_1, \ldots, \alpha_n \) in \( S \). If \( A \in R[X_1, \ldots, X_n] \) is
symmetric, then \( A(\alpha_1, \ldots, \alpha_n) \in R \).

316
As $A$ is symmetric, there exists a polynomial $T \in R[X_1, \ldots, X_n]$ such that $A(X_1, \ldots, X_n) = T(\Sigma_1, \ldots, \Sigma_n)$. For $i = 1, \ldots, n$, let us note $s_i = \Sigma_i(\alpha_1, \ldots, \alpha_n)$. Thus $A(\alpha_1, \ldots, \alpha_n) = T(s_1, \ldots, s_n)$. If $f(X) = \sum_{i=0}^n a_i X^i$, then

$$a_{n-i} = a_n(-1)^i \Sigma_i(\alpha_1, \ldots, \alpha_n) = a_n(-1)^i s_i \Rightarrow s_i = (-1)^i a_n^{-1} a_{n-i}$$

Therefore

$$A(\alpha_1, \ldots, \alpha_n) = T(-a_n^{-1} a_{n-1}, a_n^{-1} a_{n-2}, \ldots, (-1)^n a_0) \in R,$$

as required. \(\square\)

Exercise B.1 Let $f$ be a monic polynomial in $Z[X]$, with roots $\alpha_1, \ldots, \alpha_n \in C$. We take $e \in N^*$ and let $g$ be the monic polynomial in $C[X]$ with roots $\alpha_1^e, \ldots, \alpha_n^e$. Show that $g$ has its coefficients in $Z$. 

317
Appendix C

Semidirect products

In this appendix we introduce the notion of the \textit{semidirect product} of two groups, which generalizes that of the direct product. This is not usually handled in depth in elementary algebra courses.

If $H$ is a normal subgroup of a group $G$, then $K$ is said to be a \textit{complement} of $H$ if

\[ G = HK \quad \text{and} \quad H \cap K = \{e\}. \]

It is easy to see that any $g \in G$ has a unique representation as a product $hk$, with $h \in H$ and $k \in K$. Also, $G = KH$ and so $g$ has a unique representation $k'h'$, with $k' \in K$ and $h' \in H$. (It is not necessarily the case that $h' = h$ or $k' = k$.) If $K$ is a proper normal subgroup of the group $G$ and $H$ has a complement $H$, then we say that $G$ is the \textit{semidirect product} of $H$ and $K$ (the order is important).

**Proposition C.1** If $G$ is the semidirect product of $H$ and $K$, then $K$ is isomorphic to the quotient group $G/H$.

**Proof** The kernel of the quotient mapping $\phi : G \rightarrow G/H$ restricted to $K$ is $H \cap K = \{e\}$, so $\phi|_K$ is injective. To see that $\phi|_K$ is surjective, we take any element $gH \in G/H$. As $g = kh$, we have

\[ gH = khH = kH = \phi (k), \]

hence $\phi|_K$ is surjective. \hfill $\square$

If $G$ is the semidirect product of $H$ and $K$, then there is a natural bijection from the cartesian product $H \times K$ into $G$, namely

\[ \psi(h, k) = hk, \]

for all $(h, k) \in H \times K$. However, this mapping is not necessarily a group homomorphism. If $\psi$ is a homomorphism, then we say that the indirect product is an \textit{internal direct product}.

**Proposition C.2** The mapping $\psi$ is a homomorphism if and only if the elements of $H$ commute with those of $K$.

**Proof** If $\psi$ is a homomorphism, then, for $h \in H$ and $k \in K$,

\[ \psi((e, k)(h, e)) = \psi(e, k)\psi(h, e), \quad \text{i.e.,} \quad hk = kh, \]

so elements of $H$ commute with elements of $K$.  

318
Now suppose that the elements of $H$ commute with those of $K$ and let $(h, k), (h', k') \in H \times K$. Then
\[
\psi((h, k)(h', k')) = hh'kk' = hkh'k' = \psi(h, k)\psi(h', k'),
\]
so $\psi$ is a homomorphism. \hfill \Box

**Corollary C.1** The mapping $\psi$ is a homomorphism if and only if $K$ is a normal subgroup of $G$.

**Proof** If $\psi$ is a homomorphism and $k \in K$ and $g = k'h' \in G$, then
\[
gkg^{-1} = (k'h')k(k'h')^{-1} = k'(hkh^{-1})k^{-1} = k'kk^{-1} \in K,
\]
so $K \triangleleft G$.

Now let us suppose that $K \triangleleft G$ and let $h \in H$ and $k \in K$. We set $z = hkh^{-1}k^{-1}$, the commutator of $h$ and $k$. As $K \triangleleft G$, $z = (hkh^{-1})k^{-1} \in K$. In the same way, $z \in H$. However, $H \cap K = \{e\}$, which implies that $z = e$ and hence that $h$ and $k$ commute. As elements of $H$ and $K$ commute, $\psi$ is a homomorphism. \hfill \Box

**Examples** - If $G = \mathbb{Z}_6$, then there exist subgroups $H$ and $K$, isomorphic respectively to $\mathbb{Z}_3$ and $\mathbb{Z}_2$, which satisfy the conditions, so we may say that $G$ is the semidirect product of $H$ and $K$.

- Now let us consider $S_3$, with $H = A_3$, which is a normal subgroup of $S_3$, and $K = \langle e, (1 2) \rangle$.

  This subgroup is not normal: for example,
  \[
  (1 2 3)(1 2)(1 3 2) = (2 3) \notin H.
  \]

  However,
  \[
  H \cap K = \{e\} \quad HK = G.
  \]

  So $S_3$ is the semidirect product of $H$ and $K$ (and $H \simeq \mathbb{Z}_3$, $K \simeq \mathbb{Z}_2$).

- The dihedral group $D_{2n}$, $n \geq 3$ is generated by elements $a$ and $b$ such that $o(a) = n$, $o(b) = 2$ and $bab = a^{-1}$. Using the relation $bab = a^{-1}$, we see that, if $H = \langle a \rangle$ and $K = \langle b \rangle$, then $D_{2n} = HK$. If $a^s = b$, with $1 \leq s < n$, then $a^{2s} = e$ and $n/2s$. As $2s < n$, we have $n = 2s$. This is clearly impossible if $n$ is odd. If $n$ is even, then $s = \frac{n}{2}$ and
  \[
  bab = a^{\frac{n}{2}}aa^{-\frac{n}{2}} = a = a^{-1} \implies n = 2,
  \]
  a contradiction. Hence $H \cap K = \{e\}$. We have shown that $D_{2n}$ is the semidirect product of $H$ and $K$.

The first two examples show clearly that groups $G_1$ and $G_2$ may be nonisomorphic, but at the same time the semidirect product of pairs of subgroups $(H_1, K_1)$ (resp. $(H_2, K_2)$), with $H_1 \simeq H_2$ and $K_1 \simeq K_2$.

**Exercise C.1** Let $H$ be the subgroup $V_4$ of $A_4$, i.e.,
\[
V_4 = \{e, (1 2)(3 4), (1 3)(2 4), (1 4)(2 3)\}.
\]

Show that $H$ is normal in $S_4$ and hence in $A_4$ and then that $A_4$ is the semidirect product of $H$ and the subgroup $K$ generated by the 3-cycle $(1 2 3)$. Is $A_4$ a direct product of $H$ and $K$?

If $G$ is the semidirect product of $H$ and $K$, then any $g \in G$ may be written in a unique form as $g = hk$, with $h \in H$ and $k \in K$. We may write the product of two elements $g$ and $g'$ as follows
\[
gg' = (hk)(h'k') = hkh'k^{-1}kk' = h\phi_k(h')kk',
\]
319
where $\phi_k$ is the automorphism of $H$ defined by $k$, i.e.,

$$\phi_k(h) = khk^{-1},$$

for all $h \in H$. (As $H \triangleleft G$, $\phi_k(h) \in H$, so $\phi_k$ is a mapping from $H$ into $H$; checking that $\phi_k$ is an automorphism is easy.) This means that the bijection $\psi$ from $H \times K$ into $G$ defined above is a homomorphism, if we define the product on $H \times K$ by

$$(h, k)(h', k') = (h\phi_k(h), kk').$$

**Exercise C.2** Show that the mapping

$$\phi : K \rightarrow \text{Aut}(H), k \mapsto \phi_k$$

is a group homomorphism, where $\text{Aut}(H)$ is the group of automorphisms defined on $H$.

A natural question now arises. Given groups $H$ and $K$, together with a homomorphism $\phi : K \rightarrow \text{Aut}(H)$, can we construct a semidirect product based on this information? The answer is affirmative and is based on our previous analysis of the semidirect product.

**Theorem C.1** If $H$ and $K$ are groups and $G = H \times K$, their cartesian product, then from a homomorphism $\phi : K \rightarrow \text{Aut}(H)$, we may define a multiplication on $G$ such that $G$ is the semidirect product of $H$ and $K$. (We identify $H$ with $H' = H \times \{e_K\}$ and $K$ with $K' = \{e_H\} \times K$.)

**Proof** We define a multiplication on $G$ by

$$(h, k)(h', k') = (h\phi_k(h'), kk').$$

We need to show first that $G$, with this multiplication, is indeed a group. The associativity is the most difficult part. We have

$$(h, k)(h', k')(h'', k'') = (h\phi_k(h'), kk')(h'', k'')$$

$$= (h\phi_k(h')\phi_k(h''), kk'k'')$$

$$= (h\phi_k(h')\phi_k(h''), kk'k'')$$

$$= (h\phi_k(h')\phi_k(h''), kk'k'')$$

$$= (h, k)(h'k')(h'', k'')$$

For $(e_H, e_K)$ we write $(e, e)$. Then

$$(h, k)(e, e) = (h\phi_k(e), ke) = (h, k)$$

and

$$(h, k)(\phi_k^{-1}(h^{-1}), k^{-1}) = (h\phi_k(\phi_k^{-1}(h^{-1}), kk^{-1}) = (hh^{-1}, kk^{-1}) = (e, e),$$

hence $G$ is a group.

We must now show that $G$ is the desired semidirect product of $H$ and $K$ (or of $H'$ and $K'$). Clearly, $H \cap K = \{(e, e)\}$ and $HK = G$, so we only need to show that $H$ is a normal subgroup of $G$. First, we consider an element of $H$ conjugated with an element of $K$:

$$(e, k)(h, e)(e, k)^{-1} = (e, k)(h, e)(\phi_k^{-1}(e^{-1}), k^{-1})$$

$$= (e, k)(h, e)(e, k^{-1})$$

$$= (\phi_k(h), k)(e, k^{-1})$$

$$= (\phi_k(h)\phi_k(e), kk^{-1}) = (\phi_k(h), e) \in H.$$

320
Now, for the general case, we have:

\[(h, k)(h', e)(h, k)^{-1} = (h, e)(e, k)(h', e)(e, k)^{-1}(h, e)^{-1}
= (h, e)(\phi_k(h'), e)(h, e)^{-1}
= (h, e)(\phi_k(h'), e)(\phi_{e^{-1}}(h^{-1}), e^{-1})
= (h\phi_k(h')h^{-1}, e) \in H.\]

Therefore \(H\) is normal in \(G\) and \(G\) is the semidirect product of \(H\) and \(K\).

\[\]

We write \(H \rtimes_\phi K\) for this semidirect product of \(H\) and \(K\), or simply \(H \rtimes K\). We often refer to it as an external semidirect product.

It is natural to ask under what circumstances an external semidirect product is a direct product. We give a simple criterion.

**Proposition C.3** An external semidirect product is direct if and only if \(\phi\) is trivial, i.e., \(\phi_k = \text{id}_H\), for all \(k \in K\).

**Proof** We must show that \(K\) is normal in \(G\) if and only if \(\phi\) is trivial. If \(\phi\) is trivial, then

\[(h, e)(e, k)(h, e)^{-1} = (h, k)(\phi_{e^{-1}}(h^{-1}), e^{-1}) = (h, k)(h^{-1}, e) = (h\phi_k(h^{-1}), k) = (e, k) \in K,\]

because \(\phi_k = \text{id}_H\). Therefore \(K\) is normal in \(G\).

On the other hand, if \(\phi\) is not trivial, then there exist \(h\) and \(k\) such that \(\phi_k(h) \neq h\) and

\[(h, e)(e, k)(h, e)^{-1} = (h, k)(\phi_{e^{-1}}(h^{-1}), e^{-1}) = (h, k)(h^{-1}, e) = (h\phi_k(h^{-1}), k) \notin K,\]

because

\[h\phi_k(h^{-1})k = e \implies h\phi_k(h)^{-1} = e \implies h = \phi_k(h),\]

a contradiction. It follows that \(K\) is not normal in \(G\).

In general, external semidirect products are not abelian. In fact, this is always so if mapping \(\phi\) is nontrivial. In this case there exist \(h\) and \(k\) such that \(\phi_k(h) \neq h\) and

\[(h, e)(e, k) = (h, k) \neq (\phi_k(h), k) = (e, k)(h, e).\]

Consequently, if the external semidirect product is abelian, then it is a direct product. This enables us to construct a large variety of nonabelian groups.

**Remarks**

- If the external semidirect product is abelian, then it is a direct product.
- Not all groups can be written as semidirect products. For example, for \(n \geq 5\), \(A_n\) is simple, i.e., it has no nontrivial proper normal subgroup, and so cannot be written as a semidirect product.

**Application:** Groups of order \(pq\), with \(p, q\) prime and \(q < p\)

We first consider the case where \(q = 2\).
Proposition C.4 If $G$ is a group of order $2p$, with $p > 2$ prime, the $G$ is cyclic or dihedral.

PROOF From Cauchy’s theorem there exist $a, b \in G$ such that $o(a) = p$ and $o(b) = 2$. Let us set $H = \langle a \rangle$ and $K = \langle b \rangle$. As $H$ has index 2, $H$ is normal in $G$, hence

\[ bab = bab^{-1} = a^r, \]

for $1 \leq r < p$. ($r = 0$ is impossible, because in this case we would have $a = e$.) If $a^s = b$, with $1 \leq s < p$, then $a^{2s} = e$, then $p|2s$. However, $s < p$, we have $p = 2s$, which implies that $p$ is even, a contradiction. It follows that $H \cap K = \{e\}$ and $|HK| = 2p$. This in turn implies that $HK = G$ and so $G = \langle a, b \rangle$.

In addition,

\[ a^r = ba^r b = b(ab)b = a \implies a^{r^2 - 1} = e \implies p|r^2 - 1. \]

This implies that $p|r - 1$ or $p|r + 1$.

Case 1: $p|r - 1$: Here $r = 1$, because

\[ 1 \leq r < p \implies 0 \leq r - 1 < p - 1 \implies r - 1 \implies ab = ba. \]

Therefore $G$ is abelian and the order of $ab$ is $2p$. It follows that $G$ is cyclic.

Case 2: $p|r + 1$: Here $r = p - 1$, because

\[ 1 \leq r < p \implies 2 \leq r + 1 < p + 1 \implies r + 1 = p \implies r = p - 1. \]

This implies that

\[ G = \langle a, b \rangle, \quad a^p = b^2 = e, \quad bab = a^{-1}, \]

ce qui implique que $G \simeq D_{2p}$.

We now consider the general case. We need a preliminary result.

Lemma C.1 Suppose that the group $G$ is generated by the elements $a$ and $b$, whose orders are respectively $m$ and $n$. We also assume that $bab^{-1} = a^r$, for some $r \in \mathbb{Z}$. Then, for $i, j, k, l \in \mathbb{N}$,

\[ (a^i b^j)(a^k b^l) = a^{i+jr^k} b^{k+l}. \]  \hspace{1cm} (C.1)

Therefore, every element $g \in G$ can be written $g = a^s b^t$, with $0 \leq s < m$ and $0 \leq t < n$. This expression is unique if $\langle a \rangle \cap \langle b \rangle = \{e\}$.

PROOF We first prove by induction that, for all $k \in \mathbb{N}$,

\[ b^k ab^{-k} = a^{r^k}, \]  \hspace{1cm} (C.2)

For $k = 0, 1$, this is evident. Suppose now that the property is true for $k - 1$, for some $k \geq 2$. Then

\[ b^k ab^{-k} = b(b^{k-1}ab^{-k+1})b^{-1} = b(a^{r^{k-1}})b^{-1} = (bab^{-1})^{r^{k-1}}. \]

From this last expression we obtain

\[ b^k ab^{-k} = (a^r)^{r^{k-1}} = a^{-r^{k-1}} = a^{r^k}. \]

This finishes the induction.
Now, using this relation, we have
\[ b^ka^{i^{-k}} = (b^kab^{-k})^i = a^{jr^i} = b^k a^i = a^{ir^k} b^k \]
and
\[ (a^i b^k)(a^j b^l) = a^i a^{jr^k} b^k b^l = a^{i+jr^k} b^{k+l}. \]
Using the orders of the elements \(a\) and \(b\), we obtain the expressions that, for all \(g \in G\), \(g = a^i b^j\), with \(0 \leq s < m\) and \(0 \leq t < n\).

If \((a) \cap (b) = \{e\}\), then, for \(0 \leq i, j < m\) and \(0 \leq k, l < n\),
\[ a^i b^j = a^{j^{-i}} = b^{l^{-i}} = e \implies m|j-i, n|l-k \implies i-j = k-l = 0. \]
Therefore the expression \(g = a^i b^j\) is unique, if \(0 \leq s < m\) and \(0 \leq t < n\).

We will now establish an elementary result, which is useful here (and elsewhere).

**Lemma C.2** If \(n \geq 2\), then
\[ \text{Aut}(\mathbb{Z}_n) \simeq \mathbb{Z}_n^*. \]

**Proof** If \(r \in \mathbb{Z}_n^*\), then the mapping \(\phi_r : x \mapsto rx\) is an automorphism of \(\mathbb{Z}_n\), so there are at least \(\phi(n)\) automorphisms of \(\mathbb{Z}_n\). Notice that \(r\) is in fact \(\phi_r(1)\), so we have \(\phi_r(x) = x\phi_r(1)\), where \(\phi_r(1)\) is invertible.

On the other hand, if \(\phi\) is an automorphism of \(\mathbb{Z}_n\), then \(\phi(x) = x\phi(1)\), for all \(x \in \mathbb{Z}_n\). If \(\phi(1)\) is not invertible, then \(\phi(1) = 0\) or \(\phi(1)\) is a zero divisor. The first alternative is false, because this would imply that the mapping \(\phi\) takes every \(x \in \mathbb{Z}_n\) to 0. In the second case, there exists \(r \neq 0\) in \(\mathbb{Z}_n\) such that \(v\phi(1) = 0\). This implies that \(\phi(v) = 0\) and, as \(\phi(0) = 0\), \(\phi\) is not injective. It follows that \(\phi(1)\) is invertible and the result now follows.

**Proposition C.5** Let \(p\) and \(q\) be prime numbers with \(q < p\). There exists a nonabelian group of order \(pq\) if and only if \(p \equiv 1(\text{mod }q)\).

**Proof** Let us first suppose that \(p \equiv 1(\text{mod }q)\). From Lemma C.2, we know that \(|\text{Aut}(\mathbb{Z}_p)| = p - 1\).

Given that \(q/p - 1\), from Cauchy’s theorem, there exists \(a \in \text{Aut}(\mathbb{Z}_p)\) with order \(q\). We may now define a homomorphism \(\phi : \mathbb{Z}_q \rightarrow \text{Aut}(\mathbb{Z}_p)\) by associating \(1 \in \mathbb{Z}_q\) to \(a\). The homomorphism \(\phi\) is trivial, because \(a\) is not the identity on \(\mathbb{Z}_p\). Therefore, from Proposition C.3, the external semidirect product \(\mathbb{Z}_n \rtimes \mathbb{Z}_q\) is not direct, hence not abelian; its order is clearly \(pq\).

Now let us suppose that \(p \not\equiv 1(\text{mod }q)\) and that \(G\) is a group of order \(pq\). Let \(P\) (resp. \(Q\)) be a Sylow \(p\)-subgroup (resp. \(q\)-subgroup) of \(G\). We note \(s_g\) (resp. \(s_q\)) the number of such subgroups. From the Sylow theorems we know that \(s_1|q\) and \(s_p \equiv 1(\text{mod }p)\). As \(q < p\), we must have \(s_q = 1\). As every conjugate \(gPg^{-1}\), for \(g \in G\), is a Sylow \(p\)-subgroup, \(gPg^{-1} = P\), hence \(P\) is a normal subgroup of \(G\). Also, \(s_g|p\) and \(s_q \equiv 1(\text{mod }q)\). From the first property \(s_q = 1\) or \(s_q = p\). However, if \(s_q = p\), then, from the second property, \(q|p - 1\), which is false by hypothesis. Hence, \(s_q = 1\) and it follows, as in the case of \(P\), that \(Q\) is normal in \(G\). This means that \(G\) is the direct product of the cyclic subgroups \(P\) and \(Q\) and so is abelian.

There is a natural question which now arises: Can there be nonisomorphic nonabelian groups of order \(pq\)? In fact, this is not possible, as we will now see.

**Proposition C.6** If \(p, q\) are prime numbers with \(q < p\) and \(G\) is a nonabelian group of order \(pq\), then \(G\) is isomorphic to \(G'\).
PROOF Let $P$ (resp. $Q$) a Sylow $p$-subgroup (resp. $q$-subgroup) of $G$ and $P'$, $Q'$ the corresponding subgroups of $G'$. These four subgroups are cyclic, so we may write

$$P = \langle a \rangle \quad Q = \langle b \rangle \quad P' = \langle \alpha \rangle \quad Q' = \langle \beta \rangle.$$  

The relation $\langle a \rangle \cap \langle b \rangle = \{ e \}$ implies that the cardinal of $\langle a \rangle \langle b \rangle$ is $pq$. Consequently $G = \langle a \rangle \langle b \rangle$. 

In the same way, $G' = \langle \alpha \rangle \langle \beta \rangle$.

From the proof of Proposition C.5 we have $P \triangleleft G$ (resp. $P' \triangleleft G'$) and there exists $r \in \mathbb{Z}$ such that $bab^{-1} = a^r$ (resp. $s \in \mathbb{Z}$ such that $\beta \alpha \beta^{-1} = \alpha^s$). Now, using Lemma C.1, we have

$$b^q = e \implies b^q a b^{-q} = a r^q \implies a = a r^q \implies e = a r^q - 1 \implies r q \equiv 1 \pmod{p}.$$  

An analogous calculation shows that $s^q \equiv 1 \pmod{p}$. The order of $s \pmod{p}$ cannot be 1, because $G'$ are not abelian. It follows that the order of $s$ is $q$. (A similar argument shows that the order of $r \pmod{p}$ is $q$. Now let us consider the equation

$$X^q \equiv 1 \pmod{p}. \quad (C.3)$$

The solutions are of the form $s^j$, with $j = 1, \ldots, q - 1$. (If $s^k \equiv s^l \pmod{p}$, with $k < l$, then $s^{l-k} \equiv 1 \pmod{p}$, which implies that $k-l = 0$, so the solutions are distinctes.) As $r$ is a solution of the equation (C.3), there is a $j \in \{1, \ldots, q - 1\}$ such that $r \equiv s^j \pmod{p}$. We notice that $j \neq 1$, because $G$ is not abelian. We have

$$\beta^j \alpha \beta^{-j} = \alpha^{s^j} = \alpha^r,$$

because $\alpha^q = e$. If $\tilde{\beta} = \beta^j$, then $\tilde{\beta}$ is a generator of $G'$. Finally, we have $G = \langle a, b \rangle$, with $bab^{-1} = a^r$ and $G' = \langle \alpha, \tilde{\beta} \rangle$, with $\beta \alpha \beta^{-1} = \alpha^r$. We define a mapping $\phi$ from $G$ into $G'$ by

$$\phi(a) = \alpha \quad \text{and} \quad \phi(b) = \tilde{\beta}$$

and extending it in a natural way to $G$. Using Lemma C.1, we see that $\phi$ is an isomorphism. □

We can now summarize the preceding work:

**Theorem C.2** If $p$ and $q$ are prime numbers, with $q < p$, and $G$ is a group of order $pq$, then either

- $p \equiv 1 \pmod{q}$ and $G$ is cyclic, or
- $p \equiv 1 \pmod{q}$ and $G$ is either cyclic or nonabelian and isomorphic to the semidirect product $\mathbb{Z}_p \rtimes_{\phi} \mathbb{Z}_q$ defined in Proposition C.5.

**Proof** From Proposition C.5, if $p \equiv 1 \pmod{q}$, then $G$ is abelian and it follows that $G$ has an element of order $pq$ and so is cyclic. On the other hand, if $p \equiv 1 \pmod{q}$, then $G$ may be abelian or nonabelian. In the first case $G$ has an element of order $pq$ and so is cyclic. In the second case, from Proposition C.5, we know that there exists a nonabelian group of order $pq$. However, from Proposition C.6, all groups of order $pq$ are isomorphic, hence $G$ is isomorphic to the semidirect product $\mathbb{Z}_p \rtimes_{\phi} \mathbb{Z}_q$ defined in Proposition C.5. □

**Remark** Given that all nonabelian groups of order $pq$, with $q < p$, are isomorphic, we often write $\mathbb{Z}_p \rtimes \mathbb{Z}_q$ for $\mathbb{Z}_p \rtimes_{\phi} \mathbb{Z}_q$. 

324
Appendix D

Nonabelian groups of order 8

We aim to identify the nonabelian groups with order 8. If \( G \) is such a group and has an element \( x \) of order 8, then \( G \) is cyclic, so abelian. On the other hand, if all elements other than the identity \( e \) have order 2, then \( x^{-1} = x \), for all \( x \in G \) and it follows that \( G \) is abelian. Now suppose that \( G \) has an element \( x \) with order 4 and let

\[
H = \langle x \rangle = \{e, x, x^2, x^3\}.
\]

We take \( y \notin H \). Then \( Hy \neq H \) and \( G = H \cup Hy \). Suppose that there is an element \( y' \in G \setminus H \) with \( o(y') = 2 \). To simplify the notation, let us write \( y \) for \( y' \). We claim that \( yx \neq x^2y \). If so, then

\[
yx^2y = yxx = x^2xy = x^2x^2y = x^4y^2 = ee = e,
\]

then

\[
x = ex = y^2x = yyx = yx^2y = e,
\]

which is impossible. Hence \( yx \neq x^2y \), as claimed. There are two other possibilities, namely \( yx = xy \) or \( yx = x^3y \). In the first case \( G \) is abelian, so let us consider the second. Then we have \( G = \langle x, y \rangle \), \( o(x) = 4 \), \( o(y) = 2 \) and

\[
yxy = x^3yy = x^3 = x^{-1}.
\]

Therefore \( G \) is isomorphic to \( D_8 \) (and nonabelian).

Now let us suppose that every element of \( G \setminus H \) has order 4 and let \( y \in G \setminus H \). As \( o(y) = 4 \), we have \( o(y^2) = 2 \) and so \( y^2 \in H \). The only element of order 2 in \( H \) is \( x^2 \), so \( y^2 = x^2 \). We claim that \( yx \neq xy \). If this is the case, then

\[
(x^3y)^2 = x^3yx^3y = x^6y^2 = x^2y^2 = x^2x^2 = x^4 = e,
\]

which implies that \( o(x^3y) \neq 4 \), because \( x^3y \notin H \). This is a contradiction and the claim is established.

If \( yx = x^2y \), then

\[
yx = x^2yy^2y = y^3 \Rightarrow x = y^2,
\]

which is impossible, because \( o(x) = 4 \) and \( o(y^2) = 2 \). The remaining possibility is \( yx = x^3y \):

\[
yx = x^3y \Rightarrow yxy^{-1} = x^3 = x^{-1}.
\]
Thus $G$ is isomorphic to the quaternion group $Q_8$. To this more clearly, if we set
\[ i = x \quad j = y \quad k = xy, \]
then we obtain
\[ i^2 = j^2 = k^2. \]
Writing $-1$ for this common value and then abbreviating $(-1)u$ to $-u$, then we have
\[ ij = -ji = k \quad jk = -kj = i \quad ki = -ik = j. \]
We have a nonabelian group of 8 elements with the required relations. This is called the quaternion group and we note it $Q_8$.

**$D_8$ as a Galois group**

Let
\[ f(X) = -2 + X^4 \in \mathbb{Z}[X]. \]
Using the Eisenstein criterion it is easy to see that $f$ is irreducible over $\mathbb{Q}$. The roots of $f$ in $\mathbb{C}$ are $\pm \sqrt[4]{2}, \pm i \sqrt[4]{2}$ and the splitting field of $f$ in $\mathbb{C}$ may be written $E = \mathbb{Q}(i, \sqrt[4]{2})$. As $[E : \mathbb{Q}] = 8$, the cardinal of the Galois group of $f$ is 8. Consider the automorphism $\rho \in G = \text{Gal}(E/\mathbb{Q})$ such that $\rho(i) = i$ and $\rho(\sqrt[4]{2}) = i \sqrt[4]{2}$. The existence of such an automorphism is assured by Proposition 2.3 and Theorem 2.2. Now $\rho(i)^2 = i$ and
\[ \rho^3(\sqrt[4]{2}) = \rho(i \sqrt[4]{2}) = i(i \sqrt[4]{2}) = -\sqrt[4]{2}, \]
therefore $\rho^4(\sqrt[4]{2}) = \sqrt[4]{2}$. Hence $o(\rho) = 4$. Now let $\sigma \in G$ be complex conjugation. Then
\[ \sigma \circ \rho(\sqrt[4]{2}) = \sigma(i \sqrt[4]{2}) = -i \sqrt[4]{2} \quad \text{and} \quad \rho \circ \sigma(\sqrt[4]{2}) = \rho(\sqrt[4]{2}) = i \sqrt[4]{2}, \]
so $\rho$ and $\sigma$ do not commute. Thus $G$ is not abelian. As $o(\rho^2) = 2$, $G$ has at least two elements with order 2. This means that $G$ is not isomorphic to $Q_8$, which has a unique element of order 2. Hence $G$ is isomorphic to $D_8$. 

326
Appendix E

Free abelian groups and free modules

Free abelian groups

In this appendix, as is usual for abelian groups, we will use the additive notation. A group $G$ is a free abelian group if $G = \{0\}$ or $G$ is isomorphic to a direct sum, not necessarily finite, of additive groups $\mathbb{Z}$, i.e.,

$$G \cong \oplus_{i \in I} \mathbb{Z}.$$  

(We recall that $\oplus_{i \in I} \mathbb{Z}$ is the collection of sets $(n_i)_{i \in I}$, with $n_i \in \mathbb{Z}$, and only a finite number of $n_i$ nonzero.)

If $G$ is a nontrivial abelian group, i.e., $G \neq \{0\}$, then we say that a subset $B$ of $G$ is a basis, if

- $B$ generates $G$, i.e., any element $x \in G$ can be written $x = n_1 x_1 + \ldots + n_k x_k$, where the $x_i \in B$ and the $n_i \in \mathbb{Z}$;

- if, for $x_1, \ldots, x_k \in B$ and $n_1, \ldots, n_k \in \mathbb{Z}$, we have $n_1 x_1 + \ldots + n_k x_k = 0$, then $n_1 = \ldots = n_k = 0$.

(We often refer to a basis as an integral basis).

Free abelian groups are precisely those abelian groups having a basis. More precisely, we have:

**Theorem E.1** A nontrivial abelian group $G$ has a basis if and only if $G$ is a free abelian group.

**Proof** Suppose that $G$ has a basis $B$. Then the mapping

$$f : \oplus_{x \in B} \mathbb{Z} \longrightarrow G, (n_x)_{x \in B} \mapsto \sum_{x \in B} n_x x$$

is an isomorphism.

Now suppose that we have an isomorphism $f : \oplus_{i \in I} \mathbb{Z} \longrightarrow G$. For $j \in I$, let us set $\delta_j = (n_i)_{i \in I} \in \oplus_{i \in I} \mathbb{Z}$, where

$$n_i = \begin{cases} 1 & \text{if } i = j, \\ 0 & \text{otherwise}. \end{cases}$$

327
Then \( \{ f(\delta_j) \}_{j \in I} \) is a basis of \( G \).

We now consider bases of free abelian groups in more detail. We begin with an elementary lemma.

**Lemma E.1** Let \( \{ G_i \}_{i \in I} \) be a collection of abelian groups and \( H_i \) a subgroup of \( G_i \), for each \( i \in I \). Then

\[
\oplus_{i \in I} G_i / \oplus_{i \in I} H_i \cong \oplus_{i \in I} (G_i / H_i).
\]

**Proof** For \( x = (x_i)_{i \in I} + \oplus_{i \in I} H_i \), let us set

\[
f(x) = (x_i + H_i)_{i \in I}.
\]

Then \( f(x) \in \oplus_{i \in I} (G_i / H_i) \) and \( f \) is an isomorphism.

In order to prove the next theorem we will need the following elementary result from set theory.

**Proposition E.1** If \( X \) is an infinite set and \( P_{\text{fin}}(X) \) the collection of finite sets in \( X \), then the cardinal of \( X \) and that of \( P_{\text{fin}}(X) \) are equal.

**Theorem E.2** If \( G \) is a nontrivial free abelian group, then all bases of \( G \) have the same cardinal.

**Proof** Let \( B \) and \( B' \) be two bases of the free abelian group \( G \). Then we have isomorphisms

\[
f : G \to \oplus_{x \in B} \mathbb{Z} \quad \text{and} \quad f : G \to \oplus_{y \in B'} \mathbb{Z}.
\]

Let us consider \( 2G = \{ 2a : a \in G \} \). \( 2G \) is a subgroup of \( G \). From Lemma E.1,

\[
G/2G \cong (\oplus_{x \in B} \mathbb{Z})/2(\oplus_{x \in B} \mathbb{Z}) \cong \oplus_{x \in B} \mathbb{Z}/2\mathbb{Z}.
\]

In the same way

\[
G/2G \cong \oplus_{y \in B'} \mathbb{Z}/2\mathbb{Z},
\]

so we have the relation

\[
\oplus_{x \in B} \mathbb{Z}/2\mathbb{Z} \cong \oplus_{y \in B'} \mathbb{Z}/2\mathbb{Z} \quad (E.1)
\]

**Case 1** : \( |B| = m < \infty, |B'| = n < \infty \).

Using equation (E.1), we have

\[
2^m = |\oplus_{x \in B} \mathbb{Z}/2\mathbb{Z}| = |\oplus_{y \in B'} \mathbb{Z}/2\mathbb{Z}| = 2^n,
\]

therefore \( m = n \).

**Case 2** : \( |B| < \infty, |B'| = \infty \).

As in the first case, we have

\[
\oplus_{x \in B} \mathbb{Z}/2\mathbb{Z} \cong \oplus_{x \in B'} \mathbb{Z}/2\mathbb{Z},
\]

which is impossible, because \( \oplus_{x \in B} \mathbb{Z}/2\mathbb{Z} \) is finite and \( \oplus_{x \in B'} \mathbb{Z}/2\mathbb{Z} \) infinite.

**Case 3** : \( |B| = \infty, |B'| = \infty \).
The mapping $\phi$ of $P_{fin}(B)$ into $\bigoplus_{x \in B} \mathbb{Z}/2\mathbb{Z}$, where $\phi(S) = (n_x)$ for every $x \in B$, with $n_x = 1$ if and only if $x \in S$, is a bijection. We define a bijection $\phi'$ of $P_{fin}(B')$ onto $\bigoplus_{y \in B'} \mathbb{Z}/2\mathbb{Z}$ in the same way. From equation (E.1), we obtain a bijection $\psi$ from $P_{fin}(B)$ onto $P_{fin}(B')$, so these two sets have the same cardinality. Applying Proposition E.1, we obtain $|B| = |B'|$. \qed

If $G$ is a nontrivial free abelian group, then the rank of $G$ is the cardinal of a basis of $G$; if $G = \{0\}$, then the rank is 0. For this rank we write $rk(G)$.

We now consider subgroups of free abelian groups. We need to some preliminary work.

**Lemma E.2** If $G$ and $H$ are groups and $f : G \to H$, $g : H \to G$ homomorphisms such that $fg = id_H$, then

$$G \cong H \oplus \ker f.$$  

**Proof** Let $G' = g(H)$. If $g(x_1) = g(x_2)$, then $fg(x_1) = fg(x_2)$, which implies that $x_1 = x_2$, because $fg = id_H$. Hence $H$ is isomorphic to $G'$. Suppose now that $y \in G' \cap \ker f$. There exists $x \in H$ such that $g(x) = y$, because $y \in G'$. As $y \in \ker f$, $f(y) = e_H$, the identity of $H$, hence $fg(x) = ey$. As $fg = id_H$, $x = e_H$ and it follows that $y = g(e_H) = e_G$, the identity of $G$. Thus $G' \cap \ker f = e_G$. We now show that $G = G' + \ker f$. Let $y \in G$ and set $y' = gf(y)$. Then

$$f(y'^{-1}y) = f(y')^{-1}f(y) = fgf(y)^{-1}f(y) = e_H$$

and so $y'^{-1}y \in \ker f$. Thus $y$ is the product of an element in $G'$ and an element in $\ker f$. We have

$$G \cong G' \oplus \ker f \cong H \oplus \ker f,$$

as stated. \qed

**Proposition E.2** If $G$ and $H$ are abelian groups, with $H$ free, and $f : G \to H$ an epimorphism, then

$$G \cong H \oplus \ker f.$$  

**Proof** We take a basis $B$ of $H$. As $f$ is surjective, for every $x \in B$, there exists an element $y_x \in G$ such that $f(y_x) = x$. We define a homomorphism $g : H \to G$ by setting $g(x) = y_x$, for all $x \in B$. Then $fg(x) = x$, for all $x \in B$ and so $fg = id_H$. From Lemma E.2, $G \cong H \oplus \ker f$. \qed

Now we are in a position to prove an important result concerning subgroups of free abelian groups of finite rank.

**Theorem E.3** Let $G$ be a free abelian group of finite rank $n$ and $H$ a subgroup of $G$. Then $H$ is a free abelian group and

$$rkH \leq rkG.$$  

We may suppose that $G = \mathbb{Z}^n$. We will prove the result by induction on $n$. If $n = 1$ and $H \subset \mathbb{Z}$, then $H = k\mathbb{Z}$, for some $k \in \mathbb{N}$. Therefore $H = 0$ or $H \cong \mathbb{Z}$, so the statement is true for $n = 1$.

Now suppose that the result is true for $n$ and let $H \subset \mathbb{Z}^{n+1}$. The mapping

$$f : \mathbb{Z}^{n+1} \to \mathbb{Z}, (m_1, \ldots, m_{n+1}) \mapsto m_{n+1}$$

is a homomorphism and

$$\ker f = \{(m_1, \ldots, m_n, 0) : m_i \in \mathbb{Z}\} \cong \mathbb{Z}^n.$$
Clearly \( f \) restricted to \( H \) is an epimorphism onto its image. As \( \text{Im} f|_H \subset \mathbb{Z} \), from what we have seen for \( n = 1 \), \( \text{Im} f|_H \) is a free abelian group, therefore, from Proposition E.2,

\[
H \cong \text{Im} f|_H \oplus \ker f|_H.
\]

We notice that \( \ker f|_H \) is a subgroup of \( \ker f \) and recall that \( \ker f \cong \mathbb{Z}^n \), hence, from the induction hypothesis, \( \ker f|_H \) is a free abelian group and \( \text{rk} \leq n \). It follows that \( H \) is a free abelian group and \( \text{rk} H \leq 1 + n \). By induction the result is true for all \( n \in \mathbb{N} \). \( \square \)

**Exercise E.1** Show that a free abelian group \( G \) may have a subgroup \( H \) strictly included in \( G \) with the same rank.

If \( G \) is a nontrivial free abelian group and \( H \) a nontrivial subgroup, then \( G \) and \( H \) have bases. We may find bases of \( G \) and \( H \), which have a special relation to each other.

**Theorem E.4** If \( H \) is a nontrivial subgroup of rank \( r \) of a free abelian group \( G \) of rank \( n \), then \( G \) has a basis \((e_1, \ldots, e_n)\) for which there exist integers \( d_1, \ldots, d_r \in \mathbb{N}^* \) such that \( d_i|d_{i+1} \), for \( 1 \leq i < r \), and \((d_1e_1, \ldots, d_re_r)\) is a basis of \( H \).

**Proof** We will prove the result by an induction on \( n \). For \( n = 1 \), the statement is evident. Now take \( n > 1 \) and suppose that the result is true for \( m < n \). If \( (u_i)_{i=1}^n \) is a basis of \( G \), then the elements \( u \in H \) are expressions of the form \( \sum_{i=1}^n n_i u_i \), with the \( n_i \in \mathbb{Z} \). If we consider all such expressions, then there is a coefficient of minimal value in \( \mathbb{N}^* \). For different bases this minimal value could be different.

We may suppose that this is the coefficient of \( v_1 \) in some expression and we write \( l_1 \) for this coefficient. We fix \( v \in H \) with

\[
v = l_1 v_1 + \sum_{i=2}^n a_i v_i.
\]

We now divide each \( a_i \) by \( l_1 \) to obtain

\[
a_i = q_i l_1 + r_i, \quad 0 \leq r_i < l_1.
\]

We have

\[
v = l_1 (v_1 + \sum_{i=2}^n q_i v_i) + \sum_{i=2}^n r_i v_i.
\]

There is no difficulty in seeing that \((v_1 + \sum_{i=2}^n q_i v_i, v_2, \ldots, v_n)\) is a basis of \( G \). As \( l_1 \) is minimal, \( r_i = 0 \), for all \( i \). Noting \( w_1 = v_1 + \sum_{i=2}^n q_i v_i \), we have \( v = l_1 w_1 \in H \).

Now let us note \( H_0 \) the collection of elements of \( H \) whose coefficient of \( w_1 \) in the basis \((w_1, v_2, \ldots, v_n)\) is 0. \( H_0 \) is a subgroup of \( H \) and \( H_0 \cap \mathbb{Z} v = \{0\} \). In fact, \( H = H_0 \oplus \mathbb{Z} v \). To show this it remains to prove that \( H = H_0 + \mathbb{Z} v \). Let \( h = b_1 w_1 + \sum_{i=2}^n b_i v_i \in H \). Dividing \( b_1 \) by \( l_1 \), we obtain

\[
b_1 = m_1 l_1 + s_1, \quad 0 \leq s_1 < l_1,
\]

and

\[
h - m_1 v = (b_1 w_1 + \sum_{i=2}^n b_i v_i) - (m_1 l_1 w_1)
\]

\[
= (b_1 - m_1 l_1) w_1 + \sum_{i=2}^n b_i v_i
\]

\[
= s_1 w_1 + \sum_{i=2}^n b_i v_i \in H.
\]

330
As $l_1$ is minimal, $s_1 = 0$, which implies that $h - m_1v \in H_0$. It follows that $H = H_0 + \mathbb{Z}v$. We have shown that $H = H_0 \oplus \mathbb{Z}v$.

Now, $H_0$ is included in the subgroup $G_0 = \oplus_{i=1}^n \mathbb{Z}v_i$ of $G$. From the induction hypothesis, $G_0$ has a basis $(w_2, \ldots, w_n)$ and there are integers $d_2, \ldots, d_r \in \mathbb{N}^*$ such that $d_i|d_{i+1}$, for $2 \leq i < r$ and $(d_2w_2, \ldots, d_rw_r)$ is a basis of $H_0$. It is clear that $(l_1w_1, d_2w_2, \ldots, d_rw_r)$ is a basis of $H$ and $(w_1, \ldots, w_n)$ a basis of $G$. To finish, we only need to show that $l_1|d_2$. We divide $d_2$ by $l_1$:

$$d_2 = al_1 + t, \quad 0 \leq t < l_1,$$

and

$$l_1w_1 + d_2w_2 = l_1(w_1 + aw_2) + tw_2 \in H.$$

As $(w_1 + aw_2, w_2, \ldots, w_n)$ is a basis of $G$, from the minimality of $l_1$, we must have $t = 0$, which implies that $l_1|d_2$. \hfill \square

**Free modules**

Although we have already seen free modules, we first recall the definition. We define free modules over rings in much the same way as we define free groups. Indeed, a free group may be considered as a free $\mathbb{Z}$-module.

Let $R$ be a commutative ring and $M$ an $R$-module. We say that a module $M$ over $R$ is free if it has a basis, i.e., a subset $U$ with the following properties:

- $U$ is a generating set: every element $m \in M$ can be expressed in the form
  $$m = r_1u_1 + \cdots + r_su_s,$$
  with $r_i \in R$ and $u_i \in U$;

- $U$ is an independant set:
  $$r_1u_1 + \cdots + r_su_s = 0 \implies r_i = 0 \ \forall i.$$

**Theorem E.5** Any two bases of a free module $M$ over a commutative ring $R$ have the same cardinality.

**Proof** Let $M$ be a free module over the ring $R$ and $I$ a maximal ideal of $R$. Then $F = R/I$ is a field. We note $IM$ the collection of all finite sums of the form $\sum_{i=1}^m a_ix_i$, with $a_i \in I$ and $x_i \in M$. $IM$ is a submodule of $M$. We now set $V = M/IM$ and define an addition on $V$ by

$$(a + IM) + (b + IM) = (a + b) + IM.$$ 

We also define a scalar multiplication by

$$(r + I)(a + IM) = ra + IM.$$ 

Both these operations are well-defined and it is easy to check that $V$, with these operations, is a vector space over $F$.

Suppose that $B = \{x_i\}$ is a basis of $M$ and let us note $\bar{B} = \{\bar{x}_i\}$, where $\bar{x}_i = x_i + IM$. We claim that $\bar{B}$ is a basis of $V$. As $\bar{B}$ is a generating set of $M$, $\bar{B}$ is a generating set of $V$. If $\sum_{i=1}^m \bar{a}_i\bar{x}_i = 0$, with $\bar{a}_i = a_i + I$ and $a_i \in R$, then $\sum_{i=1}^m a_ix_i \in IM$. Hence there exist

331
\[ b_1, \ldots, b_n \in I \text{ such that } \sum_{i=1}^{m} a_i x_i = \sum_{i=1}^{n} b_i x_i. \] As \( \mathcal{B} \) is a basis of \( M \), for each \( i \), there is a \( b_j \) with \( a_i = b_j \), so \( a_i \in I \) and it follows that \( a_i = 0 \) in \( F \). We have shown that the \( \bar{x}_i \) form an independant set and therefore a basis of \( V \) over \( F \). As all bases of a vector space have the same cardinality, all bases of the free module \( M \) have the same cardinality. \( \square \)

The common cardinality of bases of a free \( R \)-module \( M \) is referred to as to as its \textit{rank}.

\textbf{Remark} It is well-known that all bases of a finite-dimensional vector space have the same cardinality. This is also the case for an infinite-dimensional vector space. Let \( \mathcal{B} \)

\begin{align*}
\text{Remark} \quad & \text{It is well-known that all bases of a finite-dimensional vector space have the same cardinality. This is also the case for an infinite-dimensional vector space. Let } \mathcal{B} = \{ u_i \}_{i \in I} \text{ and } \mathcal{B}' = \{ v_j \}_{j \in J} \text{ be bases of the infinite-dimensional vector space } V \text{ over the field } F. \text{ Each } x_i \text{ lies in the span of a finite set } \{ y_j \}_{j \in J_i} \text{ of } \mathcal{B}'. \text{ We claim that } J = \cup_{i \in I} J_i. \text{ Clearly } \cup_{i \in I} J_i \subset J. \text{ If } \cup_{i \in I} J_i \neq J, \text{ then the span of the } x_i \text{ is contained in the span of the } y_j \text{ such that } j \text{ is contained in at least one } J_i. \text{ However, the span of the } x_i \text{ is } V, \text{ so a subset of } \mathcal{B}' \text{ spans } V, \text{ which is impossible, because } \mathcal{B}' \text{ is a basis of } V \text{ and hence a minimal spanning set. It follows that } J = \cup_{i \in I} J_i, \text{ as claimed. Therefore}
\end{align*}

\[ |J| = |\cup_{i \in I} J_i| \leq \sum_{i \in I} |J_i| \leq |I||\emptyset| = |I|, \]

because the product of a pair of cardinals is equal to their maximum, if one of them is infinite. To show that \( |I| \leq |J| \), we use an analogous argument. Hence all bases of an infinite-dimensional vector space have the same cardinality.

We know that if \( V \) is a vector space over a field \( F \) and the dimension of \( V \) is \( n < \infty \), then there can be no independant subset of \( V \) with more than \( n \) elements. We have an analogous result for free modules.

\textbf{Theorem E.6} If \( M \) is a free module of rank \( n < \infty \) over a commutative ring \( R \), then any independant subset of \( M \) is composed of at most \( n \) elements.

\textbf{Proof} Let \( \{ b_1, \ldots, b_m \} \) be an independant subset of \( M \). The mapping

\[ \phi : R^m \longrightarrow M, r \longmapsto \sum_{i=1}^{m} r_i b_i \]

is a monomorphism of \( R \)-modules. Hence there exists a monomorphism of \( R \)-modules \( \psi \) from \( R^n \) into \( R^m \). Now let \( I \) be a maximal ideal of \( R \) and \( IR^n \) the collection of sums of the form \( \sum_{i=1}^{n} a_i x_i, \) with \( a_i \in I \) and \( x_i \in R^n \). The set \( IR^n \) is a submodule of \( R^n \). We define \( IR^m \) in an analogous fashion. The mapping

\[ \Psi : R^m/(IR^m) \longrightarrow R^n/(IR^n), x + IR^m \longmapsto \psi(x) + IR^n \]

is a well-defined monomorphism of \( R \)-modules. In addition, the mapping

\[ \Gamma : (R/I)^m \longrightarrow R^m/(IR^m), (r_1 + I, \ldots, r_m + I) \longrightarrow (r_1, \ldots, r_m) + IR^m \]

is a well-defined isomorphism of \( R \)-modules. In the same way, \( (R/I)^n \) is isomorphic, as an \( R \)-module, to \( R^n/(IR^n) \). Therefore we have an \( R \)-module monomorphism \( \alpha \) from \( (R/I)^m \) into \( (R/I)^n \). However, \( (R/I)^m \) and \( (R/I)^n \) are vector spaces over the field \( R/I \). We claim that \( \alpha \) is an \( R/I \)-linear mapping. We notice that, for \( x \in (R/I)^m \) (or \( x \in (R/I)^n \)), \( (r + I)x = rx \) and so \( \alpha((r + I)x) \) is defined. Then

\[ \alpha((r + I)x) = \alpha(rx) = r \alpha(x) = (r + I) \alpha(x) \]

and it follows that \( \alpha \) is \( R/I \)-linear. As \( \alpha \) is a linear monomorphism, we have \( m \leq n \). \( \square \)
Exercise E.2 In the proof of Theorem E.6 we stated that the mapping $\Psi$ is a monomorphism. Show that this is indeed the case.

We may extend this result to $R$-modules of infinite rank.

Theorem E.7 If $M$ is a free module, with infinite basis $B$, over a commutative ring $R$, and $A$ an independent subset of $M$, then $|A| \leq |B|$.

Proof The elements of $A$ are finite linear combinations of elements of $B$. For $x \in A$, we let $f(x)$ be the finite subset of $B$ composed of the elements of $B$ in the linear combination of $x$. We thus obtain a mapping of $A$ into $\mathcal{P}_{\text{fin}}(B)$, the collection of finite subsets of $B$. If $E \in \mathcal{P}_{\text{fin}}(B)$ has $n$ elements and $\langle E \rangle$ be the $R$-module generated by $E$, then, from Theorem E.6, any independent subset of $\langle E \rangle$ has at most $n$ elements. As $f^{-1}(E) \subset \langle E \rangle$ and is a set composed of independent elements, we have $|f^{-1}(E)| \leq n$. Thus

$$|A| = \sum_{n>0} \sum_{E \in \mathcal{P}_{\text{fin}}(B)} |f^{-1}(E)| \leq \sum_{n>0} n|B|,$$

because the cardinal of the collection of finite subsets of a given infinite set is the cardinal of the set itself. We obtain

$$|A| \leq |B| \sum_{n>0} n = |B||N^*|,$$

where we have again used the result concerning finite subsets of a given infinite set. To finish, we observe that, for two infinite cardinals $X$ and $Y$, we have

$$|X||Y| = \max(|X|, |Y|)$$

and so we obtain

$$|A| \leq |B|,$$

as required. \hfill \Box

We may use Theorem E.6 to prove another result concerning free modules.

Theorem E.8 Let $R \subset S$ be integral domains, with respective fraction fields $K$ and $L$. If $S$ is a free $R$-module of rank $n < \infty$, then $[K : L] = n$.

Proof Let $X = \{x_1, \ldots, x_m\}$ be an independent subset of the $K$-vector space $L$. Each $x_i$ can be written in the form $\frac{u_i}{v_i}$, with $(u_i, v_i) \in S \times S^*$. If we set $v = v_1 \cdots v_m$, then the set $\{sx_1, \ldots, sx_m\}$ is independent in the $R$-module $S$. From Theorem E.6, we have $m \leq n$. It follows that $L$ is a finite extension of $K$ and $[K : L] \leq n$.

Now let $B$ be a basis of the $R$-module $S$. Clearly $B$ is an independent subset of the $K$-vector space $L$, so $n \leq [K : L]$. Therefore $[K : L] = n$. \hfill \Box

Corollary E.1 Under the conditions of Theorem E.8, if $B$ is a basis of the free $R$-module $S$, then $B$ is a basis of the $K$-vector space $L$.

Proof If $B$ is a basis of the free $R$-module $S$, then $B$ is an independent subset of the $K$-vector space $L$. From Theorem E.8, we have $\text{rk} S = [K : L]$, so $B$ is a basis of $L$. \hfill \Box

Torsion and free modules

333
Our aim here is to prove a result giving us a condition for a module to be free. However, before turning to modules, we will recall the Smith normal form of a matrix. For a ring \( R \) we will write \( \mathcal{M}_{m,n}(R) \) for the collection of \( m \times n \) matrices with coefficients in \( R \). If \( m = n \), i.e., in the case where the matrices are square matrices, we will use the notation \( \mathcal{M}_n(R) \). We have the following result:

If \( R \) is a principal ideal domain and \( A \in \mathcal{M}_{m,n}(R) \), then there exist invertible matrices \( P \in \mathcal{M}_m(R) \) and \( Q \in \mathcal{M}_n(R) \) such that

\[
PAQ = B = \begin{bmatrix}
D & X \\
Y & Z
\end{bmatrix},
\]

where \( D = \text{diag}(d_1, \ldots, d_r) \) is a diagonal matrix, with nonzero entries \( d_i \) such that \( d_i \vert d_{i+1} \), for \( i = 1, \ldots, r - 1 \), and \( X, Y \) and \( Z \) are matrices of zeros of respective dimensions \( r \times (n - r) \), \((m - r) \times r \) and \( r \times (n - r) \). The \( d_i \) are unique up to multiplication by an invertible element of \( R \). Such a matrix \( B \) is called a Smith normal form of the matrix \( A \). (A good introduction to the Smith normal form may be found in [5].)

We say that a module \( M \) over a ring \( R \) is \textit{finitely generated} if there are \( m_1, \ldots, m_s \in M \) such that every element \( m \in M \) can be expressed in at least one way as

\[
m = r_1 m_1 + \cdots + r_s m_s,
\]

with the \( r_i \in R \). The module \( M \) is \textit{free} if it has a \textit{basis}, i.e., a set \( U \) which has the properties:

- \( U \) is a generating set: every element \( m \in M \) can be expressed as
  \[
m = r_1 u_1 + \cdots + r_s u_s,
\]
  with the \( u_i \in U \) and the \( r_i \in R \);
- \( U \) is an independant set:
  \[
  r_1 u_1 + \cdots + r_s u_s = 0 \implies r_i = 0, \quad \text{for all } i.
  \]

We now consider modules over integral domains. If \( R \) is an integral domain and \( M \) an \( R \)-module, then an element \( u \in M \) is a \textit{torsion element} if there exists \( r \in R^\times \) such that \( ru = 0 \). The torsion elements form a submodule of \( M \), which we note \( tM \). If \( tM = 0 \), then we say that \( M \) is \textit{torsion-free}. The following result relates finitely generated, torsion-free and free modules.

**Proposition E.3** Let \( R \) be principal ideal domain and \( M \) a finitely generated \( R \)-module. Then \( M \) has a finite base if and only if \( M \) is torsion-free.

**Proof** Suppose that \( M \) has a finite basis \( U = (u_1, \ldots, u_s) \). If \( m = r_1 u_1 + \cdots + r_s u_s \neq 0 \), then there is at least one \( r_i \), which is nonzero. If \( d \in R^\times \) and \( dm = 0 \), then

\[
(dr_1) u_1 + \cdots + (dr_i) u_i + \cdots + (dr_s) u_s = 0 \implies dr_1 = \cdots = dr_i = \cdots = dr_s = 0,
\]

because \( U \) is a basis. As \( R \) is an integral domain and \( r_i \neq 0 \), \( d = 0 \), which is a contradiction. Hence, \( M \) is torsion-free.

We now begin with the hypothesis that \( M \) is torsion-free. Let \( U = (u_1, \ldots, u_s) \) be a generating set of \( M \). We use an induction on \( s \) to show that \( M \) is free. If \( s = 1 \), then \( M = Ru \), so \( \{u\} \) is a generating set. If \( ru = 0 \) and \( r \neq 0 \), then \( u \in tM \). As \( M \) is torsion-free, this is impossible, hence \( U = (u) \) is a basis. Now suppose that \( s > 1 \) and that the result is true for up to \( s - 1 \) elements.
in a generating set. Let \( r_1, \ldots, r_s \in R \), not all 0, be such that \( \sum_{i=1}^{s} r_i u_i = 0 \). Let \( C \) be the \( 1 \times s \) matrix \([r_1]\). From our discussion of the Smith normal form, we know that there are invertible matrices, \( P \in \mathcal{M}_1(R) \) and \( Q \in \mathcal{M}_s(R) \), such that
\[
P[r_1 \ldots r_s]Q = [d \ 0 \ldots 0].
\]
If \( P = [p] \), then \( p \) is invertible and we obtain
\[
[r_1 \ldots r_s]Q = [d' \ 0 \ldots 0],
\]
where \( d' = p^{-1}d \). If we set \( V = Q^{-1}U \), then \( V = (v_1, \ldots, v_s) \) clearly generates \( M \). Also,
\[
0 = [r_1 \ldots r_s]U = [r_1 \ldots r_s]QV = [d' \ 0 \ldots 0]V \implies d'v_1 = 0.
\]
As \( d' \neq 0 \) and \( M \) is torsion-free, \( v_1 = 0 \). Hence, the set \( (v_1, \ldots, v_s) \) generates \( M \). By the induction hypothesis, \( M \) has a finite basis. This finishes the proof. \( \square \)
Appendix F

The Chinese remainder theorem

We give two versions of the Chinese remainder theorem, one as a corollary of the other. We recall that two ideals $I$ and $J$ in a commutative ring $R$ are said to be coprime if $I + J = R$.

**Theorem F.1** Let $I_1, \ldots, I_n$ be ideals in a commutative ring $R$ which are coprime in pairs, i.e., $I_i + I_j = R$ if $i \neq j$. If $a_1, \ldots, a_n \in R$, then there exists a solution $\alpha \in R$ to the system of congruences

\[
\begin{align*}
x & \equiv a_1 \pmod{I_1} \\
& \quad \vdots \\
x & \equiv a_n \pmod{I_n}.
\end{align*}
\]

Any two solutions are congruent modulo $I_1 \cap \cdots \cap I_n$.

**Proof** We fix $i$ and take $j \neq i$. As $I_i + I_j = R$, there exist $b_j \in I_i$, $c_j \in I_j$ such that $b_j + c_j = 1$. Then

\[
\prod_{j \neq i} (b_j + c_j) = 1.
\]

We now expand the left hand side of the equation to obtain $x_i + y_i = 1$, where $x_i$ is the sum of the terms containing $a b_j$ and $y_i = \prod_{j \neq i} c_j$. Then

\[
y_i \equiv 1 \pmod{I_i} \quad \text{and} \quad y_i \equiv 0 \pmod{I_j}, j \neq i.
\]

We now set

\[
\alpha = a_1 y_1 + a_2 y_2 + \cdots + a_n y_n.
\]

Clearly $\alpha$ has the required properties.

If $\beta$ is another solution to the system of congruences, then $\beta \equiv a_i (\mod I_i)$, for all $i$. This is equivalent to saying that $\beta - \alpha \equiv 0 (\mod I_i)$, for all $i$, which in turn is equivalent to the statement

$\beta - \alpha \in \cap_{i=1}^{n} I_i$, i.e., $\beta \equiv \alpha (\mod \cap_{i=1}^{n} I_i)$.

**Corollary F.1** Under the conditions of the theorem

\[
R/(\cap_{i=1}^{n} I_i) \cong R/I_1 \times \cdots \times R/I_n.
\]
PROOF We define a mapping $\phi$ from $R$ into $\prod_{i=1}^{n} R/I_i$ by setting

$$\phi(x) = (x + I_1, \ldots, x + I_n).$$

It is not difficult to see that $\phi$ is a ring homomorphism. From Theorem F.1, we know that, if $(a_1, \ldots, a_n) \in R^n$, then there exists an $a \in R$ such that $a \equiv a_i (\text{mod } I_i)$, for all $i$. It follows that the mapping $\phi$ is surjective. As $\text{Ker } \phi = \cap_{i=1}^{n} I_i$, we have

$$R/(\cap_{i=1}^{n} I_i) \simeq R/I_1 \times \cdots \times R/I_n,$$

from the first isomorphism theorem for rings. \qed
Appendix G

Lattices in euclidian space

A subgroup $\Lambda$ of the additive group of $\mathbb{R}^n$ is said to be discrete if there exists an open ball of radius $\epsilon > 0$, centered on the origin, $B(0, \epsilon)$, such that $B(0, \epsilon) \cap \Lambda = \{0\}$. If, in addition, the span of $\Lambda$ is $\mathbb{R}^n$, then we say that $\Lambda$ is a lattice in $\mathbb{R}^n$, or, more briefly, a lattice.

**Example** If $V = \{v_1, \ldots, v_n\}$ is an independent set in $\mathbb{R}^n$, then the set

$$\Lambda = \{v \in \mathbb{R}^n : v = \sum_{i=1}^{n} a_i v_i, a_i \in \mathbb{Z}\} \quad (G.1)$$

is a lattice. In the case where $v_i = e_i$, where $(e_i)_{i=1}^{n}$ is the standard basis of $\mathbb{R}^n$, then we call this lattice the standard integer lattice in $\mathbb{R}^n$.

**Bases of lattices**

If $\{v_1, \ldots, v_k\}$ is an independent set in $\mathbb{R}^n$ such that the lattice $\Lambda$ can be written

$$\Lambda = \{v \in \mathbb{R}^n : v = \sum_{i=1}^{n} a_i v_i, a_i \in \mathbb{Z}\},$$

then we say that $(v_i)_{i=1}^{n}$ is a basis of $\Lambda$. Our first task is to show that all lattices have a basis, hence they are of the form $(G.1)$.

**Lemma G.1** Let $\Lambda \subset \mathbb{R}^n$ be a lattice and $b_1, \ldots, b_k$, with $k < n$, be linearly independent. We set $L = \text{span}(b_1, \ldots, b_k)$. Then there exists a point $v \in \Lambda \setminus L$ which minimizes the distance to $L$.

**Proof** Let $A$ be the closed parallelepiped generated by $b_1, \ldots, b_k$:

$$A = \{u \in \mathbb{R}^n : u = \sum_{i=1}^{k} \alpha_i b_i, \ 0 \leq \alpha_i \leq 1\}.$$ 

$A$ is a compact subset of $\mathbb{R}^n$. We claim that there is a point $v \in \Lambda \setminus L$ which minimizes the distance to $A$. To see this, we first choose $a \in \Lambda \setminus L$ and set $\rho = \text{dist} (a, A)$. We note

$$A_\rho = \{u \in \mathbb{R}^n : \text{dist} (u, A) \leq \rho\}.$$
As \( A_p \) is closed and bounded, it is compact. If \( A_p \cap \Lambda \) is infinite, then it contains a convergent subsequence \( (x_n) \) composed of distinct elements. By hypothesis, there is an open ball \( B(0, \epsilon) \cap \Lambda = \{0\} \). As \( \Lambda \) is a subgroup of the additive group of \( \mathbb{R}^n \), \( x_s - x_t \in \Lambda \), when \( s \neq t \), so \( \|x_s - x_t\| \geq \epsilon \). This implies that the sequence \( (x_n) \) is not convergent and it follows that the set \( A_p \cap \Lambda \) is finite. Also, as \( a \in A_p \cap \Lambda \), there are points in this set which are not in \( L \). Hence \( A_p \cap \Lambda \setminus L \neq \emptyset \) and this set is finite. We may thus choose \( v \in A_p \cap \Lambda \setminus L \) which minimizes the distance to \( A \). Clearly, \( v \) minimizes the distance from \( \Lambda \setminus L \) to \( A \), which establishes the claim.

Let \( w \in \Lambda \setminus L \) and \( y \in L \). Then
\[
y = \sum_{i=1}^{k} \gamma_i b_i,
\]
with \( \gamma_i \in \mathbb{R} \). If we set
\[
z = \sum_{i=1}^{k} [\gamma_i] b_i,
\]
then \( z \in \Lambda \), hence \( w - z \in \Lambda \). Also, \( w - z \notin L \). (If \( w - z \in L \), then \( w = (w - z) + z \in L \), a contradiction.) Therefore \( w - z \in \Lambda \setminus L \). In addition,
\[
y - z = \sum_{i=1}^{k} (\gamma_i - [\gamma_i]) b_i \in A,
\]
therefore
\[
\text{dist} (w, y) = \text{dist} (w - z, y - z) \geq \text{dist} (w - z, A) \geq \text{dist} (v, A) = \text{dist} (v, L)
\]
and so \( v \) minimizes the distance from \( \Lambda \setminus L \) to \( L \).

We need another preliminary result.

**Lemma G.2** Let \( \Lambda \subset \mathbb{R}^n \) be a lattice and \( b_1, \ldots, b_n \in \Lambda \) independant. We set \( L_0 = \{0\} \) and \( L_k = \text{span}(b_1, \ldots, b_k) \), for \( k = 1, \ldots, n \). Then, for \( k = 1, \ldots, n \), there exists \( u_k \in (L_k \cap \Lambda) \setminus L_{k-1} \) which minimizes the distance from \( (L_k \cap \Lambda) \setminus L_{k-1} \) to \( L_{k-1} \).

**Proof** Let \( \phi \) be the linear isomorphism from \( L_k \) onto \( \mathbb{R}^k \) defined by
\[
\phi(\alpha_1 b_1 + \cdots + \alpha_k b_k) = (\alpha_1, \ldots, \alpha_k).
\]
It is not difficult to see that \( \phi(L_k \cap \Lambda) \) is a lattice in \( \mathbb{R}^k \). From Lemma G.1 we know that there is a point \( u \in \phi(L_k \cap \Lambda) \setminus \phi(L_{k-1}) \) which minimizes the distance to \( \phi(L_{k-1}) \). It follows that \( \phi^{-1}(u) \) minimizes the distance from \( (L_k \cap \Lambda) \setminus L_{k-1} \) to \( L_{k-1} \).

We may now show that every lattice has a basis. We remark that any lattice \( \Lambda \) in \( \mathbb{R}^n \), from the definition of a lattice, must contain a set of \( n \) independant vectors. We may see this in the following way: Each vector \( e_i \) of the standard basis is a linear combination of a finite number of elements of \( \Lambda \). Taking all the elements of \( \Lambda \) in these linear combinations, we obtain a finite generating set of \( \mathbb{R}^n \), from which we may extract a minimum generating set of \( \mathbb{R}^n \), i.e., a basis.

**Notation** We will write \{\( x \)\} for the fractional part of the number \( x \in \mathbb{R} \), i.e., \( \{x\} = x - \lfloor x \rfloor \).

**Theorem G.1** Let \( \Lambda \subset \mathbb{R}^n \) be a lattice and \( b_1, \ldots, b_n \subset \Lambda \) independant. We define \( L_0, L_1, \ldots, L_n \) an in Lemma G.2. From the same lemma, we know that there exists \( u_k \in (L_k \cap \Lambda) \setminus L_{k-1} \) minimizing the distance to \( L_{k-1} \). Then the vecteurs \( u_1, \ldots, u_n \) form a basis of the lattice \( \Lambda \).
PROOF Let us set \( \Lambda_k = \Lambda \cap L_k \). We will show by induction that the set \( \{u_1, \ldots, u_k\} \) is a \( \mathbb{Z} \)-basis of \( \Lambda_k \), i.e., an independant set such that

\[
\Lambda_k = \{ v \in \mathbb{R}^n : v = \sum_{i=1}^{k} a_i u_i, \ a_i \in \mathbb{Z} \}.
\]

As \( \Lambda = \Lambda_n \), this will be sufficient to prove the theorem.

For \( k = 1 \) we have

\[
u_1 = \alpha_1 b_1,
\]

for some \( \alpha_1 \neq 0 \) in \( \mathbb{R} \). If \( v \in \Lambda_1 \), then

\[
v = \beta b_1,
\]

for some \( \beta \in \mathbb{R} \). We claim that \( \mu = \frac{\beta}{\alpha_1} \) is an integer. If not, then \( 0 < \{ \mu \} < 1 \). Setting \( u'_1 = v - \lfloor \mu \rfloor u_1 \), we have, since \( v = \mu u_1 \),

\[
u'_1 = \mu u_1 - \lfloor \mu \rfloor u_1 = \{ \mu \} u_1.
\]

However, \( u'_1 \in \Lambda_1 \setminus \{0\} \) and is closer to the origin than \( u_1 \), a contradiction. Thus \( \frac{\beta}{\alpha_1} \in \mathbb{Z} \). It now follows that

\[
v = \beta b_1 = \frac{\beta}{\alpha_1} u_1,
\]

with \( \frac{\beta}{\alpha_1} \in \mathbb{Z} \). So \( \{u_1\} \) is a \( \mathbb{Z} \)-basis of \( \Lambda_1 \).

We now suppose that the result is true for \( k - 1 \) and consider the case \( k \). If

\[
x = \sum_{i=1}^{k} \gamma_i b_i \in L_k,
\]

then, since \( L_{k-1} \) is a vector space,

\[
\text{dist} (x, L_{k-1}) = \text{dist} (\gamma_k b_k, L_{k-1}) = |\gamma_k| \text{dist} (b_k, L_1).
\]

Also,

\[
u_k = \sum_{i=1}^{k} \alpha_i b_i,
\]

with \( \alpha_1, \ldots, \alpha_k \in \mathbb{R} \) and \( \alpha_k \neq 0 \). If \( v \in \Lambda_k \), then

\[
v = \sum_{i=1}^{k} \beta_i b_i,
\]

with \( \beta_1, \ldots, \beta_k \in \mathbb{R} \). We claim that \( \mu = \frac{\beta_k}{\alpha_k} \) is an integer. If this is not the case, then \( 0 < \{ \mu \} < 1 \).

We set \( u'_k = v - \lfloor \mu \rfloor u_k \). Then

\[
u'_k = v - \mu u_k + \{ \mu \} u_k
\]

\[
= \sum_{i=1}^{k} \beta_i b_i + \beta_k b_k - \frac{\beta_k}{\alpha_k} \left( \sum_{i=1}^{k-1} \alpha_i b_i + \alpha_k b_k \right) + \{ \mu \} \left( \sum_{i=1}^{k-1} \alpha_i b_i + \alpha_k b_k \right)
\]

\[
= \sum_{i=1}^{k} \beta_i b_i - \lfloor \mu \rfloor \sum_{i=1}^{k-1} \alpha_i b_i + \{ \mu \} \alpha_k b_k
\]

\[
= \sum_{i=1}^{k-1} (\beta_i - \lfloor \mu \rfloor \alpha_i) b_i + \{ \mu \} \alpha_k b_k.
\]

340
The element \( u'_k \) belongs to \( \Lambda_k \setminus L_{k-1} \) and the distance from \( u'_k \) to \( L_{k-1} \) is that of \( \{ \mu \} \alpha_kb_k \). However, the distance of \( \{ \mu \} \alpha_kb_k \) to \( L_{k-1} \) is that of \( \{ \mu \} u_k \), which is strictly less than that of \( u_k \), a contradiction. Hence \( \mu = \frac{\beta_k}{n_k} \in \mathbb{Z} \), as claimed. Therefore \( v - \mu u_k \in \Lambda_{k-1} \). Applying the induction hypothesis we obtain that \( v - \mu u_k \) is an integer linear combination of \( u_1, \ldots, u_{k-1} \) and it follows that \( v \) is an integer linear combination of \( u_1, \ldots, u_k \). This finishes the induction step and hence the proof.

**Corollary G.1** A lattice in \( \mathbb{R}^n \) is a free abelian group of rank \( n \).

**Parallelepipeds**

If \( \Lambda \subset \mathbb{R}^n \) is a lattice and \( u = (u_i)_{i=1}^n \) a basis of \( \Lambda \), then the set

\[
\Pi_u = \left\{ v = \sum_{i=1}^n \alpha_iu_i : 0 \leq \alpha_i < 1, \right\}
\]

is called the fundamental parallelepiped of the basis \( u \). If the basis \( u \) is understood, then we usually write \( \Pi \) in place of \( \Pi_u \).

**Proposition G.1** If \( \Pi \) is a fundamental parallelepiped of the lattice \( \Lambda \), then, for each element \( x \in \mathbb{R}^n \), there exist unique elements \( y \in \Lambda \) and \( z \in \Pi \) such that \( x = y + z \).

**Proof** Let us consider the fundamental parallelepiped \( \Pi = \Pi_u \) of the basis \( u \). As \( u \) is a basis of \( \mathbb{R}^n \), we can write \( x = \sum_{i=1}^n \alpha_iu_i \), with \( \alpha_i \in \mathbb{R} \). If we set

\[
y = \sum_{i=1}^n \alpha_iu_i \quad \text{and} \quad z = \sum_{i=1}^n \{ \alpha_i \}u_i,
\]

then \( y \in \Lambda \), \( z \in \Pi \) and \( x = y + z \).

Suppose now that there two decompositions: \( x = y_1 + z_1 = y_2 + z_2 \). Then

\[
z_1 = \sum_{i=1}^n \alpha_iu_i \quad \text{and} \quad z_2 = \sum_{i=1}^n \beta_iu_i,
\]

with \( 0 \leq \alpha_i < 1 \) and \( 0 \leq \beta_i < 1 \), for all \( \alpha_i, \beta_i \). We obtain

\[
y_1 - y_2 = z_2 - z_1 = \sum_{i=1}^n \gamma_iu_i,
\]

with \( \gamma_i = \beta_i - \alpha_i \). Clearly, \( |\gamma_i| < 1 \). As \( y_1 - y_2 \in \Lambda \), we must have \( \gamma_i = 0 \), for all \( \gamma_i \), which implies that \( y_1 = y_2 \) and \( z_1 = z_2 \). \( \square \)

**Corollary G.2** Let \( \Lambda \subset \mathbb{R}^n \) be a lattice and \( \Pi \) a fundamental parallelepiped of \( \Lambda \). Then the translates \( \{ y + \Pi : y \in \Lambda \} \) cover \( \mathbb{R}^n \) without overlapping.

**Proof** From Proposition G.1, if \( x \in \mathbb{R}^n \), then \( x = y + z \), with \( y \in \Lambda \) and \( z \in \Pi \); hence \( x \) belongs to the translate \( y + \Pi \). Therefore the translates cover \( \mathbb{R}^n \). If \( x \in (y_1 + \Pi) \cap (y_2 + \Pi) \), then \( x = y_1 + z_1 = y_2 + z_2 \), with \( z_1, z_2 \in \Pi \). From the uniqueness of the decomposition of \( x \), we have \( y_1 = y_2 \) (and \( z_1 = z_2 \)), so there can be no overlapping of translates. \( \square \)
We recall that the volume of a Lebesgue measurable set $A$ in $\mathbb{R}^n$ is defined by
\[ \text{vol } A = \int_{\mathbb{R}^n} \chi_A(x) dx, \]
where $\chi_A$ is the characteristic function of $A$. The next elementary result is important for what follows.

**Proposition G.2** Let $A$ be a Lebesgue measurable set in $\mathbb{R}^n$ and $T$ a linear automorphism of $\mathbb{R}^n$. Then
\[ \text{vol } T(A) = |\text{det } T| \text{vol } A. \]

**Proof** Using the "change of variable" formula (see for example [20]), we have
\[ \int_{\mathbb{R}^n} \chi_A(x) dx = \int_{\mathbb{R}^n} \chi_A \circ T(x) |\text{det } T| dx = |\text{det } T| \int_{\mathbb{R}^n} \chi_{T^{-1}(A)}(x) dx. \]
Hence
\[ \text{vol } A = |\text{det } T| \text{vol } T^{-1}(A) \Rightarrow \text{vol } T(A) = |\text{det } T| \text{vol } A, \]
as required. \qed

**Corollary G.3** If $X \subset \mathbb{R}^n$ is Lebesgue measurable and $r > 0$, then
\[ \text{vol } rX = r^n \text{vol } X. \]

We now introduce a result which will enable us to define an important invariant of a lattice.

**Theorem G.2** Let $u = (u_i)_{i=1}^n$ and $v = (v_i)_{i=1}^n$ be bases of the lattice $\Lambda \subset \mathbb{R}^n$ and $\Pi_u, \Pi_v$ the corresponding fundamental parallelepipeds. Then
\[ \text{vol } \Pi_u = \text{vol } \Pi_v. \]

**Proof** Let $T$ be the linear automorphism of $\mathbb{R}^n$ defined by
\[ T(u_i) = v_i, \]
for $i = 1, \ldots, n$. The matrix of $T$ in the basis $u$ is the matrix representation $A$ of the basis $v$ in terms of the basis $u$. The coefficients are integers, since each $v_i \in \Lambda$ and $u$ is a basis of $\Lambda$. Similarly, the matrix representation $B$ of the basis $u$ in terms of the basis $v$ has only integer coefficients. As $AB = BA = I_n$, we have $|\text{det } T| = 1$. Therefore, from Proposition G.2,
\[ \text{vol } T(\Pi_u) = \text{vol } \Pi_u. \]
As $T(\Pi_u) = \Pi_v$, we have the result. \qed

The volume of a fundamental parallelepiped of a lattice is called the determinant of the lattice. For the determinant of the lattice $\Lambda$, we write $\text{det } \Lambda$. If $u = (u_i)_{i=1}^n$ is a basis of $\Lambda$, $e = (e_i)_{i=1}^n$ the standard basis of $\mathbb{R}^n$ and $T$ the linear automorphism defined by
\[ T(e_i) = u_i, \]
for $i = 1, \ldots, n$, then from Proposition G.2 we have
\[ \text{vol } \Pi_u = \text{vol } T(\Pi_e) = |\text{det } T| \text{vol } \Pi_e. \]
As \( \text{vol } \Pi = 1 \) and \( \det T \) is the determinant of the matrix \( U \) whose columns are the vectors \( u_1, \ldots, u_n \), we have
\[
\det \Lambda = |\det U|.
\]
This justifies the use of the term \( \det \Lambda \) for the volume of a fundamental parallelepiped \( \Pi_u \).

**Minkowski’s convex body theorem**

In order to prove Minkowski’s theorem we will prove another result, namely Blichfeldt’s theorem.

**Theorem G.3** (Blichfeldt) Let \( \Lambda \) be a lattice in \( \mathbb{R}^n \) and \( X \) a Lebesgue measurable set in \( \mathbb{R}^n \) such that \( \text{vol } X > \det \Lambda \). Then there are distinct points \( x_1, x_2 \in X \) such that \( x_1 - x_2 \in \Lambda \).

**Proof** Let \( \Pi \) be a fundamental parallelepiped of \( \Lambda \). For each \( y \in \Lambda \), we set
\[
X_y = ((\Pi + y) \cap X) - y.
\]
Then \( X_y + y = (\Pi + y) \cap X \). From Corollary G.2 these sets form a partition of \( X \). Therefore
\[
\sum_{y \in \Lambda} \text{vol } (X_y + y) = \text{vol } X > \det \Lambda = \text{vol } \Pi.
\]
We now set
\[
f(x) = \sum_{y \in \Lambda} \chi_{X_y}(x),
\]
for all \( x \in \mathbb{R}^n \). Then
\[
\sum_{y \in \Lambda} \int_{\Pi} \chi_{X_y}(x)dx = \sum_{y \in \Lambda} \text{vol } (X_y \cap \Pi) = \sum_{y \in \Lambda} \text{vol } (X_y \cap \Pi + y),
\]
by the invariance of Lebesgue measure with respect to translation. Consequently,
\[
\int_{\Pi} f(x)dx = \sum_{y \in \Lambda} \text{vol } ((X_y + y) \cap (\Pi + y)) = \sum_{y \in \Lambda} \text{vol } (X_y + y) > \text{vol } \Pi.
\]
From this we deduce that
\[
\int_{\Pi} (f(x) - 1)dx > 0
\]
and so \( f(x) > 1 \) for some \( x \in \Pi \). As \( f(x) \in \mathbb{N} \cup \{+\infty\} \), we must have \( f(x) \geq 2 \), which implies that there exist distinct values elements \( y_1, y_2 \in \Lambda \) such that \( X_{y_1} \cap X_{y_2} \neq \emptyset \). Let \( z \in X_{y_1} \cap X_{y_2} \). Then
\[
z + y_1 = x_1 \in X \quad \text{and} \quad z + y_2 = x_2 \in X,
\]
which implies that \( x_1 - x_2 = y_1 - y_2 \in \Lambda \). \( \square \)

We may now prove Minkowski’s convex body theorem.

**Theorem G.4** (Minkowski) Let \( \Lambda \subset \mathbb{R}^n \) be a lattice and \( A \) a convex subset of \( \mathbb{R}^n \), with \( \text{vol } A > 2^n \det \Lambda \). In addition suppose that \( A \) is centrally symmetric. Then \( A \) contains a nonzero lattice point. If \( A \) is compact, then it is sufficient to suppose that \( \text{vol } A \geq 2^n \det \Lambda \).

343
PROOF We set $X = \frac{1}{2}A$. From Corollary G.3,

$$\text{vol } X = \frac{1}{2^n} \text{vol } A > \text{det } \Lambda.$$ 

By Theorem G.4 there exist distinct elements $x_1, x_2 \in X$ such that $x = x_1 - x_2 \in \Lambda$. Now, $2x_1, 2x_2 \in A$ and, as $A$ is symmetric about the origin, $-2x_2 \in A$. Since $A$ is convex, we have

$$x = x_1 - x_2 = \frac{1}{2}(2x_1) + \frac{1}{2}(-2x_2) \in A.$$ 

Now we consider the case where $A$ is compact and $\text{vol } A = 2^n \text{det } \Lambda$. Let $\rho > 1$. Then, by Corollary G.3,

$$\text{vol } \rho A = \rho^n \text{vol } A > 2^n \text{det } \Lambda,$$

so there is a nonzero lattice point $x_\rho$ in $\rho A$. Now let $(\rho_m)$ be a sequence in $(1, +\infty)$ converging to 1. Then $(\frac{x_{\rho_m}}{\rho_m})$ is a sequence in $A$. As $A$ is compact, the sequence has a convergent subsequence $(\frac{x_{\rho_m}}{\rho_m})$. If $x = \lim \frac{x_{\rho_m}}{\rho_m}$, then $x = \lim x_{\rho_m}$. For $m, n$ sufficiently large, $x_{\rho_m} - x_{\rho_n} = 0$, because $\Lambda$ is a discrete group. This implies that $x = x_{\rho_m}$ for some $m$, hence $x \in \Lambda$. Also, as $x_{\rho_m} \neq 0$, $x \neq 0$. $\square$

**Sublattices**

If $\Lambda, \Lambda_0 \subset \mathbb{R}^n$ are lattices and $\Lambda_0 \subset \Lambda$, then we say that $\Lambda_0$ is a sublattice of $\Lambda$. As $\Lambda_0$ is a subgroup of $\Lambda$, we may consider the index of $\Lambda_0$ in $\Lambda$.

**Proposition G.3** The index of $\Lambda_0$ in $\Lambda$, $[\Lambda : \Lambda_0]$, is finite.

**Proof** We fix the fundamental parallelepipeds $\Pi$ and $\Pi_0$ of $\Lambda$ and $\Lambda_0$ respectively. Let $x + \Lambda_0$ be a coset in the quotient group $\Lambda/\Lambda_0$. From Proposition G.1 there is a unique decomposition $x = y + z$, with $y \in \Lambda_0$ and $z \in \Pi_0$. As $x, y \in \Lambda$, we have $z \in \Lambda$. It follows that $z$ is a representative of the coset $x + \Lambda_0$; each coset has a representative in $\Lambda \cap \Pi_0$. As $\Lambda$ is a discrete group and $\Pi_0$ a compact set, the set $\Lambda \cap \Pi_0$ is finite, there can only be a finite number of cosets. $\square$

In fact, we can determine $[\Lambda : \Lambda_0]$ from the determinants of the two lattices. We claim that, if $x_1 + \Lambda_0 = x_2 + \Lambda_0$, with $x_1, x_2 \in \Lambda \cap \Pi_0$, then $x_1 = x_2$. First we notice that $x_1 - x_2 \in \Lambda$, because both $x_1, x_2 \in \Lambda$. If $v = (v_1, \ldots, v_n)$ is a basis of $\Lambda_0$, then the coefficients of $x_1$ and $x_2$ in this basis have values in the interval $[0, 1]$, which implies that the coefficients of $x_1$ and $x_2$ have values in the interval $(-1, 1)$. Since $x_1 - x_2 \in \Lambda_0$, these coefficients are integers, hence the only possible value is $0$ and so $x_1 = x_2$, as claimed. It follows that there are exactly $[\Lambda \cap \Pi_0]$ cosets in $\Lambda/\Lambda_0$.

The lattice $\Lambda$ is a free abelian group of rank $n$ and the sublattice $\Lambda_0$ is also a free abelian group of the same rank. From Theorem E.4, there exists a basis $(u_1, \ldots, u_n)$ of $\Lambda$ for which there exist integers $d_1, \ldots, d_n \in \mathbb{N}^*$ such that $(d_1 u_1, \ldots, d_n u_n)$ is a basis of $\Lambda_0$. If $x \in \Lambda \cap \Pi_0$, then

$$x = a_1 u_1 + \cdots + a_n u_n = b_1 d_1 u_1 + \cdots + b_n d_n u_n,$$

where $a_i \in \mathbb{Z}$ and $0 \leq b_i < 1$. As $a_i, d_i \in \mathbb{Z}$, we have $b_i = \frac{a_i}{d_i} \in \mathbb{Q}$. Given that $0 \leq b_i < 1$, we have $d_i$ possibilities for $b_i$, namely $0, \frac{1}{d_i}, \ldots, \frac{d_i - 1}{d_i}$. It follows that $0, 1, \ldots, d_i - 1$ are the only possibilities for $a_i$. Therefore for $x$ there are $d_1 \cdots d_n$ possibilities, i.e., $|\Lambda/\Lambda_0| = d_1 \cdots d_n$.

We now consider the automorphism $T$ of $\mathbb{R}^n$ defined by

$$T(u_i) = d_i u_i,$$

344
for $i = 1, \ldots, n$. We now suppose that $\Pi$ is the fundamental parallelepiped of $\Lambda$ corresponding to the basis $(u_i)$ and $\Pi_0$ that of $\Lambda_0$ corresponding to the basis $(d_i u_i)$. As $|\det T| = d_1 \cdots d_n$, from Proposition G.2 we have

$$\operatorname{vol} \Pi_0 = d_1 \cdots d_n \operatorname{vol} \Pi.$$  

We have shown that

**Theorem G.5**

$$[\Lambda : \Lambda_0] = \frac{|\det \Lambda_0|}{\det \Lambda}.$$

We defined a lattice in $\mathbb{R}^n$ at the beginning of this appendix as a discrete subgroup whose span is $\mathbb{R}^n$. We now consider the case where we do not have a condition on the span.

**Theorem G.6** If $H$ is a discrete, nontrivial subgroup of $\mathbb{R}^n$, then $H$ is isomorphic to a lattice in $\mathbb{R}^r$, where $r$ is the dimension of the vector subspace generated by $H$.

**Proof** Let $e_1, \ldots, e_r \in H$ be a maximal linearly independent subset in $H$ and $T$ the fundamental domain defined by the $e_i$, i.e.,

$$T = \{ x \in \mathbb{R}^n : x = \sum_{i=1}^r a_i e_i, \ 0 \leq a_i < 1 \}.$$

The closure of $T$ is

$$\bar{T} = \{ x \in \mathbb{R}^n : x = \sum_{i=1}^r a_i e_i, \ 0 \leq a_i \leq 1 \}.$$

If $x \in H$, then $x = \sum_{i=1}^r b_i e_i$, with $b_i \in \mathbb{R}$. For an integer $j$ we set $x_j = jx - \sum_{i=1}^r [jb_i] e_i$. We claim that $x_j \in H \cap \bar{T}$. As $x_j = \sum_{i=1}^r (jb_i - [jb_i]) e_i$ and $0 \leq jb_i - [jb_i] < 1$, we have $x_j \in T$. Also, $H$ is a subgroup of $\mathbb{R}^n$, so $[jb_i] e_i \in H$, for all $i$, and so their sum is also in $H$. Clearly $jx \in H$, hence $x_j \in H$. This proves the claim.

If we take $j = 1$, then we have $x_1 = x - \sum_{i=1}^r [b_i] e_i \in H \cap \bar{T}$. As $H$ is discrete $H \cap \bar{T}$ is a finite set, because $\bar{T}$ is compact. It follows that $H \cap T$ is also finite, so there exist only a finite number of choices for $x_1$ and it follows that $H$ is generated by the distinct values of the $x_1$ and $e_i$. (Any element $y \in H$ is the translation of an element $x \in H \cap T$ by a sum of the form $u = \sum_{i=1}^r a_i e_i$, with $a_i \in \mathbb{Z}$, which belongs to $H$.)

Our next step is to show that the $b_i$ are rational. As there are only a finite number of distinct elements in $H \cap T$ and all the $x_j$ belong to this set, there must be $x_j = x_k$, with $j \neq k$. Then, using the linear independance of the $e_i$, we obtain

$$(j - k)b_i = [jb_i] - [kb_i],$$

for all $i$, and it follows that the $b_i$ are rational.

Since the distinct values of $x_1$ are linear combinations of the $e_i$ with rational coefficients, $H$ is generated by a finite number of linear combinations of the $e_i$ with rational coefficients. If $d$ is the $\text{lcm}$ of the denominators of these coefficients, then $d \neq 0$ and $dH \subset \sum_{i=1}^r \mathbb{Z} e_i$. Thus $dH$ is a subgroup of a free abelian group of rank $r$, hence is free of rank at most $r$. Given that $dH \simeq H$, $H$ is free, and since $H \supset \sum_{i=1}^r \mathbb{Z} e_i$, the rank of $H$ is at least $r$, and hence exactly $r$. Since $H$ is a free abelian group of rank $r$, it is isomorphic to the standard integer lattice $\mathbb{Z}^r$ of $\mathbb{R}^r$.

To conclude we need to show that $r$ is equal to the dimension of the vector subspace generated by $H$. Let us write $S$ for this subspace and $A$ for the subspace generated by the $e_i$. It is sufficient to show that $S = A$. In the previous part of the proof we showed that $H$ is generated by a finite number of linear combinations of the $e_i$ with rational coefficients, thus $S \subset A$. However, $S$ must contain all linear combinations of the $e_i$, hence $A \subset S$. Therefore $S = A$, as required. \hfill \Box
Appendix H

Kronecker products of matrices

Let \( A \) be an \( m \times n \) matrix and \( B \) a \( p \times q \) matrix over a commutative ring \( R \). The Kronecker (or tensor) product of \( A \) and \( B \), written \( A \otimes B \), is the \( mp \times nq \) matrix defined as follows:

\[
A \otimes B = \begin{bmatrix}
  a_{11}B & \cdots & a_{1n}B \\
  \vdots & \ddots & \vdots \\
  a_{m1}B & \cdots & a_{mn}B
\end{bmatrix}
\]

In general, \( A \otimes B \neq B \otimes A \), because we do not have \( mp = nq \). However, even if this is the case, for example when both \( A \) and \( B \) are square matrices of the same dimension, it is not in general true that \( A \otimes B = B \otimes A \). For example,

\[
\begin{bmatrix}
  1 & 2 \\
  3 & 4
\end{bmatrix} \otimes \begin{bmatrix}
  1 & 0 \\
  2 & 3
\end{bmatrix} = \begin{bmatrix}
  1 & 0 & 2 & 0 \\
  2 & 3 & 4 & 6 \\
  3 & 0 & 4 & 0 \\
  6 & 9 & 8 & 12
\end{bmatrix}
\]

and

\[
\begin{bmatrix}
  1 & 0 \\
  2 & 3
\end{bmatrix} \otimes \begin{bmatrix}
  1 & 2 \\
  3 & 4
\end{bmatrix} = \begin{bmatrix}
  1 & 2 & 0 & 0 \\
  3 & 4 & 0 & 0 \\
  2 & 4 & 3 & 6 \\
  6 & 8 & 9 & 12
\end{bmatrix}.
\]

We are particularly interested in the case where \( R \) is a field \( F \) and \( A \) and \( B \) square matrices. Then \( A \otimes B \) is an \( mn \times mn \) matrix, with coefficients in \( F \).

It is interesting to notice what happens when \( A = I_m \). We have

\[
I_m \otimes B = \text{diag}(B \ldots B),
\]

i.e., \( I_m \otimes B \) is a matrix with \( m \) blocks \( B \) on the diagonal and 0 elsewhere. We leave it to the reader to determine the form of the matrix \( A \otimes I_n \).

Let us write \( c_{ij} \) for the column vector

\[
(a_{1i}b_{1j} \ldots a_{1i}b_{nj} a_{2i}b_{1j} \ldots a_{2i}b_{nj} \ldots a_{mi}b_{1j} \ldots a_{mi}b_{nj})^t.
\]
We notice that the pairs of indices \((k, l)\) in \(a_k b_j\) follow the order
\[(1, 1), (1, 2), \ldots, (1, n), (2, 1), \ldots, (2, n), \ldots, (m, 1), \ldots, (m, n).\]

We define a mapping
\[
B : F^m \times F^n \longrightarrow F^{mn}, (uv) \longmapsto u \otimes v,
\]
where
\[
u \otimes v = (u_1 v_1, \ldots, u_1 v_n, u_2 v_1, \ldots, u_2 v_n, \ldots, u_m v_1, \ldots, u_m v_n).
\]
The mapping \(B\) is clearly bilinear. Also, if \((e_i)_{i=1}^m\) (resp. \((f_j)_{j=1}^n\)) is the standard basis of \(F^m\) (resp. \(F^n\)), then the products \(e_i \otimes f_j\), for \(1 \leq i \leq m\) and \(1 \leq j \leq n\), form the standard basis of \(F^{mn}\). It is not difficult to see that
\[
(A \otimes B)(e_i \otimes f_j) = c_{ij} = A e_i \otimes B f_j.
\]
Using the bilinearity of \(B\) we obtain
\[
(A \otimes B)(u \otimes v) = Au \otimes Bv,
\]
for every pair \((u, v) \in F^m \times F^n\).

We have seen that in general \(A \otimes B \neq B \otimes A\). However, if the matrices \(A\) and \(B\) are square matrices, then \(A \otimes B\) and \(B \otimes A\) are conjugate, i.e., there exists an invertible \(mn \times mn\) matrix \(P\) such that
\[
P(A \otimes B)P^{-1} = B \otimes A.
\]
To see this, let \(\phi\) be the linear endomorphism defined on \(F^{mn}\) by the matrix \(A \otimes B\) and the ordered basis
\[
B_1 = (e_1 \otimes f_1, \ldots, e_1 \otimes f_n, \ldots, e_m \otimes f_1, \ldots, e_m \otimes f_n).
\]
The coordinates of \(\phi(e_i \otimes f_j)\) in this basis are the elements of the column vector \(c_{ij}\). Suppose now that we order the basis elements differently to obtain the new ordered basis
\[
B_2 = (e_1 \otimes f_1, \ldots, e_m \otimes f_1, e_1 \otimes f_2, \ldots, e_m \otimes f_2, \ldots, e_1 \otimes f_n, \ldots, e_m \otimes f_n).
\]
Then the coordinate vector of \(\phi(e_i \otimes f_j)\) in this ordered basis is
\[
(a_{i1} b_{j1}, a_{i2} b_{j1}, \ldots, a_{im} b_{j1}, a_{i1} b_{j2}, \ldots, a_{im} b_{j2}, \ldots, a_{i1} b_{nj}, \ldots, a_{im} b_{nj})^t.
\]
However, this is the column \(c_{ij}'\) of the matrix \(B \otimes A\). Hence the representation of the linear endomorphism \(\phi\) in the bases \(B_1\) and \(B_2\) is \(B \otimes A\) and it follows that \(A \otimes B\) and \(B \otimes A\) are conjugate.

We can now prove the main result of this appendix.

**Theorem H.1** Let \(A \in \mathcal{M}_m(F)\) and \(B \in \mathcal{M}_n(F)\). Then
\[
tr(A \otimes B) = tr(A) tr(B) \quad \text{and} \quad \det(A \otimes B) = \det(A)^n \det(B)^m.
\]

**Proof** For the trace we have
\[
tr(A \otimes B) = \sum_{i=1}^m \sum_{j=1}^n a_{ij} b_{jj} = \sum_{i=1}^m a_{ii} \sum_{j=1}^n b_{jj} = tr(A) tr(B).
\]

347
The determinant is more subtle. We claim that

$$A \otimes B = (A \otimes I_n)(I_m \otimes B).$$

In fact, for $u \in F^m$ and $v \in F^n$,

$$(A \otimes I_n)(I_m \otimes B)(u \otimes v) = (A \otimes I_n)(u \otimes Bv) = Au \otimes Bv = (A \otimes B)(u \otimes v),$$

which proves the claim. Now, using the fact that $A \otimes I_n$ and $I_n \otimes A$ are conjugate, we obtain

$$\det(A \otimes B) = \det(A \otimes I_n) \det(I_m \otimes B) = \det(I_n \otimes A) \det(I_m \otimes B) = \det(A)^n \det(B)^m,$$

as given in the statement of the theorem. \qed

**Corollary H.1** $A \otimes B$ is invertible if and only if both $A$ and $B$ are invertible.
Appendix I

Infinite products

Let $a_1, a_2, \ldots$ be an infinite sequence of nonzero complex numbers. We say that the infinite product $\prod_{n \geq 1} a_n$ converges if there is a number $\gamma$ such that the sequence $(\prod_{n=1}^i a_i)$ converges to $\gamma$. An infinite product may converge to 0, even if all the elements $a_n$ are nonzero. For example, it is sufficient to take $a_n = \frac{1}{2^n}$, for all $n$. However, we are interested in the case where $\gamma$ is nonzero.

Lemma I.1 The infinite product $\prod_{n \geq 1} a_n$ converges to a nonzero element $\gamma$ if and only if, for all $\epsilon > 0$, there is an $n(\epsilon)$ such that

$$|a_n a_{n+1} \cdots a_{n+k} - 1| < \epsilon$$

for all $n \geq n(\epsilon)$ and $k \geq 0$.

**Proof** Suppose that $\prod_{n \geq 1} a_n$ converges to $\gamma \neq 0$ and let $\epsilon > 0$. Choose a positive number $\delta < |\gamma|$ such that $\frac{2\delta}{|\gamma| - \delta} < \epsilon$. There exists $n_1$ with the property

$$|a_1 \cdots a_i - \gamma| < \delta,$$

for all $i \geq n_1$. In particular,

$$|a_1 \cdots a_{1+i+k'} - a_1 \cdots a_{1+i}| \leq |a_1 \cdots a_{1+i+k'} - \gamma| + |\gamma - a_1 \cdots a_{1+i}| < 2\delta,$$

for all $i \geq n_1$ and $k' \geq 1$. Also,

$$|a_1 \cdots a_{1+i+k'} - a_1 \cdots a_{1+i}| = |a_1 \cdots a_{1+i+k'} - a_1 \cdots a_{1+i+k'} - 1|$$

$$= |a_1 \cdots a_{1+i} - \gamma + \gamma|a_1 \cdots a_{1+i+k'} - 1|$$

$$\geq (|\gamma| - |a_1 \cdots a_{1+i} - \gamma|)|a_1 \cdots a_{1+i+k'} - 1|$$

$$\geq (|\gamma| - \delta)|a_2 \cdots a_{1+i+k'} - 1|,$$

and so, setting $n = 2 + i$ and $k = k' - 1$, we obtain

$$|a_n \cdots a_{n+k} - 1| \leq \frac{2\delta}{|\gamma| - \delta} < \epsilon,$$

for all $n \geq 2 + n_1 = n(\epsilon)$ and $k \geq 0$.  

349
We now consider the converse. Taking $\epsilon = \frac{1}{2}$, we see that there exists $n(\frac{1}{2}) \geq 1$ such that
\[
\frac{3}{2} \geq |a_n \cdots a_{n+k}| \geq \frac{1}{2},
\] (I.1)
for all $n \geq n(\frac{1}{2})$ and $k \geq 0$. To simplify the notation, we set $n(\frac{1}{2}) = n_2$. We consider the sequence of partial products
\[
p_n = \prod_{i=n_2}^{n_2+n-1} a_i
\]
and let $\epsilon > 0$. Let $n$ be sufficiently large so that $n_2 + n \geq n(\frac{2}{3})$. Then we have
\[
|p_n - p_{n+k}| = |a_{n_2} \cdots a_{n_2+n-1} - a_{n_2} \cdots a_{n_2+n+k-1}|
\]
\[
= |a_{n_2} \cdots a_{n_2+n-1}||1 - a_{n_2+n} \cdots a_{n_2+n+k-1}| \leq \frac{3}{2} \cdot \frac{2\epsilon}{3} = \epsilon,
\]
where we have used the inequality (I.1). Thus the $p_n$ form a Cauchy sequence and hence converge. The condition (I.1) shows that the limit is nonzero. \qed

Remark By Lemma I.1, if we take $\epsilon > 0$ and $n$ is sufficiently large, then $|a_n - 1| \leq \epsilon$. Hence if the infinite product converges to a nonzero element, then $\lim a_n = 1$. Therefore, if the infinite product $\prod_{n \geq 1}(1 + a_n)$ converges, then we have $\lim a_n = 0$.

Definition The infinite product $\prod_{n \geq 1}(1 + a_n)$ is said to be absolutely convergent if the product $\prod_{n \geq 1}(1 + |a_n|)$ converges (necessarily to a nonzero element).

Lemma I.2 The infinite product $\prod_{n \geq 1}(1 + a_n)$ is absolutely convergent if and only if the infinite sum $\sum_{n \geq 1} a_n$ is absolutely convergent.

Proof First we notice that the function $f(x) = e^x - x - 1$ is nonnegative for $x \geq 0$: $f(0) = 0$ and $f'(x) = e^x - 1 > 0$, for $x > 0$. Then
\[
|a_1| + \cdots + |a_n| < (1 + |a_1|) \cdots (1 + |a_n|)
\]
\[
\leq e^{|a_1|} \cdots e^{|a_n|} = e^{|a_1 + \cdots + |a_n|}.
\]
Therefore the sums $\sum_{i=1}^{n} |a_i|$ are bounded if and only if the products $\prod_{i=1}^{n}(1 + |a_i|)$ are bounded and the result follows. \qed

We conclude this appendix with a fundamental theorem.

Theorem I.1 Suppose that the infinite product $\prod_{n \geq 1}(1 + a_n)$ is absolutely convergent. Then

- **a.** the infinite product $\prod_{n \geq 1}(1 + a_n)$ converges to a nonzero element;
- **b.** the infinite product $\prod_{n \geq 1}(1 + a_n)$ is convergent after any rearrangement of the terms;
- **c.** all such rearrangements yield the same limit.

Proof **a.** From Lemma I.2 the absolute convergence of the sum $\sum_{n \geq 1} a_n$ is equivalent to the absolute convergence of the product $\prod_{n \geq 1}(1 + a_n)$. Let $\epsilon > 0$. By Lemma I.1, for all $n$ sufficiently large and all $k \geq 0$, we have
\[
|(1 + |a_n|) \cdots (1 + |a_{n+k}|) - 1| < \epsilon.
\]
But

\[ |(1 + a_n) \cdots (1 + a_{n+k}) - 1| \leq (1 + |a_n|) \cdots (1 + |a_{n+k}|) - 1 \]

\[ = |(1 + |a_n|) \cdots (1 + |a_{n+k}|) - 1| < \epsilon, \]

and so, from Lemma I.1, the product \( \prod_{n \geq 1} (1 + a_n) \) converges to a nonzero element.

(The first inequality merits an explanation. The expression \( (1 + a_n) \cdots (1 + a_{n+k}) - 1 \) is a sum of monomials in \( a_n, \ldots, a_{n+k} \), whose absolute value is bounded by the sum of the corresponding monomials in \( |a_n|, \ldots, |a_{n+k}| \), the value of which is \( (1 + |a_n|) \cdots (1 + |a_{n+k}|) - 1 \).)

b. Let \( \sigma : \mathbb{N} \rightarrow \mathbb{N} \) be a bijection, which is not the identity. The convergence of \( \sum_{n \geq 1} |a_n| \) implies that of \( \sum_{n \geq 1} |a_{\sigma(n)}| \) so, by Lemma I.2, \( \prod_{n \geq 1} (1 + |a_{\sigma(n)}|) \) is convergent. From part a, we deduce that \( \prod_{n \geq 1} (1 + a_{\sigma(n)}) \) is convergent.

c. For \( n \geq 1 \) we set \( p_n = (1 + a_1) \cdots (1 + a_n) \) and \( p'_n = (1 + \sigma(a_1)) \cdots (1 + \sigma(a_n)) \). Let \( k_1 < \cdots < k_m \) denote the elements of \( \{1, \ldots, n\} \setminus \{\sigma(1), \ldots, \sigma(n)\} \) and \( k'_1 < \cdots < k'_l \) the elements of \( \{\sigma(1), \ldots, \sigma(n)\} \setminus \{1, \ldots, n\} \). Then

\[ \frac{p_n}{p'_n} = \frac{(1 + a_{k_1}) \cdots (1 + a_{k_m})}{(1 + a'_{k'_1}) \cdots (1 + a'_{k'_l})}. \]

Considering the numerator we have

\[ |(1 + a_{k_1}) \cdots (1 + a_{k_m}) - 1| \leq (1 + |a_{k_1}|) \cdots (1 + |a_{k_m}|) - 1 \]

\[ \leq \exp(|a_{k_1}| + \cdots + |a_{k_m}|) - 1 \]

\[ < \exp \left( \sum_{i=k_1}^{\infty} |a_i| \right) - 1. \]

As \( n \to \infty \), we have \( k_1 \to \infty \), so, from Lemma I.2, we have \( \sum_{i=k_1}^{\infty} |a_i| \to 0 \). This shows that the numerator tends to 1 as \( n \to \infty \). An analogous argument shows that this is also the case for the denominator. This proves part c. \( \square \)
