Abstract

In this paper, a novel fractional-order recursive integral terminal sliding mode (FORITSM) control is proposed for nonlinear systems in the presence of external disturbances with unknown bounds. The proposed control approach provides an easy-to-implement solution capable of zeroing the sliding variable in a finite-time (FnT) by adding a fractional-order command filter. Moreover, the reaching phase is eliminated, and FnT convergence of the system states is proved. The proposed technique has also a chattering alleviation property, which is beneficial for practical cases, as the control of quadrotor UAVs presented in the paper. Finally, a simulation case study on a quadrotor system is illustrated to show the effectiveness of the proposed FORITSM control, also with respect to classical methods.

KEYWORDS: Chattering alleviation, FnT, fractional-order recursive integral terminal sliding mode, full-order sliding mode, reaching phase, uncertain systems.

1 | INTRODUCTION

Sliding mode control (SMC) is a powerful easy-to-implement control technique with remarkable robustness properties in case of systems affected by disturbances and unavoidable modelling uncertainties. The goal of SMC in its classical version is to compel the behavior of a dynamical system according to a manifold, i.e., the so-called “sliding surface”, specified by a function known as “sliding variable”, via a discontinuous controller depending on the sliding variable itself.

Once the sliding variable is zeroed, that is a “sliding mode” is enabled, it can be proved that the controlled system is insensitive to the uncertainty terms fulfilling a matched condition. Moreover, the key feature of the SMC method is the capability to enable a finite-time convergence of the sliding variable towards the sliding surface, thus implying an equivalent reduced order dynamics, for which asymptotic stability of the system trajectories is guaranteed. However, more recently, advanced techniques extended the original SMC concept by enhancing the robustness properties of the controlled system through the introduction of integral methods, or by introducing state constraints, or enabling also a FnT convergence of the system trajectories by using terminal sliding modes.

1.1 | Background and motivations

In this paper, we consider the family of the terminal sliding mode (TSM) controllers. As previously mentioned, this type of control law guarantees that, if the sliding mode exists, this allows to regulate the system trajectories in FnT. Nevertheless, the
main drawback of TSM is the occurrence of singularity in the control signal, which could cause system instability. Specifically, in such technical concerns and future challenges have been discussed in the perspective of a broader scope of technological advances such as cyber-physical systems, artificial intelligence, and network systems, providing a summary of the state of the art in TSM control theory and applications.

To avoid the singularity problem, nonsingular TSM (NTSM) controllers have been developed in recent years, see where a finite-time stabilizing method based on the SMC strategy was devised to handle this issue. Aside from singularity, TSM and NTSM control approaches suffer the generation of chattering phenomenon due to the discontinuity of the control function, resulting in high-frequency oscillations of the system states, which can damage mechanical components and lead to input saturation when employed in nonlinear systems.

Several methods have been introduced in the literature for reducing chattering, including the boundary layer method, the high-order sliding-mode method, and the disturbance estimation method. In the case of boundary layer approach, the saturation function or sigmoid function are adopted. This choice gives rise to a “pseudo-sliding mode”, since only a vicinity of the sliding surface is reached, thus possibly causing the loss of robustness of the system in front of disturbances. As for high-order sliding-mode (HOSM) control approaches, they allow to confine the discontinuity to the derivative of the control input while the signal actually fed into the plant is continuous. The disturbance estimation method is instead based on the design of an asymptotic disturbance observer to compensate for the disturbance, thus allowing a smoother control signal. Among many other approaches, recently, the combination of internal model principle and adaptive sliding mode control, as proposed in, allows a reduction of the control authority to dominate the uncertainties with a consequent chattering reduction.

Another drawback of the presented SMCs is the length of the reaching phase (RP) and the sensitivity of the controlled system to perturbation during such an interval. Many works have been developed to address these problems, see e.g., . As for integral HOSM controllers, these are instead discussed in for uncertain nonlinear systems to remove the RP, although the input singularity generated by the sliding function is not studied in depth.

Moreover, to avoid the problem of “complexity explosion”, command filtering can be used. For example, in a command filtered and adaptive control is proposed, while a command filter using fractional-order dynamics in the design of sliding mode manifold is presented. A command filtered based-backstepping technique is suggested in, and a FnT adaptive control is developed in. Also command-filter-based adaptive fuzzy FnT control approaches have been proposed as those in.

The second part of the paper addresses the tracking control of quadrotors subject to complex disturbances using the proposed command-filter method. Many existing control approaches for the quadrotors system have been proposed in the literature review, for example, in the paper, an adaptive recursive sliding mode control was designed to achieve a finite time stability with online estimation of the unknown disturbances. The authors of proposed a nonlinear implicit PID with feedback gains to reject constant perturbations of unknown magnitude, where the optimal feedback gains are solved by linear matrix inequalities. In, model predictive contouring control was used to obtain optimal quadrotor flight takes. Similarly, the work presented a comparative study of nonlinear-model-predictive and differential-flatness-based controllers for quadrotor system. The work developed in proposed a model-free control with time-prescribed convergence taking out uncertainties and disturbances. In, a robust-integral-signum-error was developed to compensate for the external disturbances. Reference combined neural network with backstepping technique for quadrotor landing. In, a robust control algorithm was designed to address to the autonomous landing problem of quadrotor UAV on mobile platform. Paper proposed a recursive SMC based on nonlinear extended state observer (ESO) for the trajectory tracking of 6-DOF hierarchical with external disturbances and uncertainties. In, a nonsingular terminal sliding mode controller was applied to follow desired quadrotor’s position. Similarly, proposed a finite-time sliding-mode observer to estimate the full state and recognize uniformly Lipschitz disturbances. The authors of developed a control strategy for autonomous quadrotor vehicle with external disturbances using SMC and backstepping approaches. In, an intelligent control strategy based on reinforcement learning was developed for quadrotor vehicle.

1.2 Contributions

This main contribution of this paper is the design of a novel robust fractional-order FnT control for perturbed nonlinear systems, capable of alleviating chattering phenomena and without singularity. Differently from the existing literature, where a reduction of the reaching phase is adopted, here, making reference to a command-filter based fractional-order (FO) recursive nonsingular terminal SMC is presented for the first time, to the best of the authors’ knowledge. By employing the fractional-order of the input in the controller, chattering reduction of the input is achieved. In the presence of external perturbations, the presented Lyapunov-based analysis shows that the system trajectories under the proposed control action can converge to the origin in FnT.
Finally, to assess the proposed strategy in a practical example, a quadrotor dynamics is considered and several simulations in different scenarios are provided. Overall, more in detail, the contributions of this paper are summarized as follows:

(i) To improve the convergence of the standard integer-order FnT command filter and avoid an “explosion of complexity”, a fractional-order finite-time command filter based on recursive nonsingular terminal SMC is introduced for full-order nonlinear system.

(ii) The fractional-order control input is produced in a nonsingular fractional-order integral form rather than a standard signum function, which is useful for reducing control input chattering. Furthermore, when compared to integral HOSM controllers\[17\], the FORITSM control only has two layers of sliding manifolds, which makes it easier to build for high-order systems.

(iii) Based on this fractional-order recursive structure of the control law, the RP is eliminated, thus enhancing the robustness of the controlled system.

(iv) The proposed control method has been applied for quadrotor dynamics and compared with the work developed in\[12\].

1.3 | Outline of the paper
The paper is organized as follows. After some preliminaries and the problem statement in Section 2, the main results on the proposed fractional-order finite-time control are given in Section 3. The application to the tracking control problem for a quadrotor dynamics is addressed in Section 4 while simulations are illustrated in Section 5. Finally, some conclusions are gathered in Section 6.

Notation
The main notation and operators used in the paper are hereafter recalled. Let \( x \in \mathbb{R} \), then the absolute value of \( x \), denoted by \(|x|\), is defined as \(|x| = x \) if \( x \geq 0 \), and \(|x| = -x \) if \( x < 0 \). The function \( \text{sign}(x) \) is defined as \( \text{sign}(x) = 1 \) for \( x > 0 \), \( \text{sign}(x) = -1 \) for \( x < 0 \), and \( \text{sign}(x) = 0 \) for \( x = 0 \). For \( \gamma \geq 0 \), one has that \( \text{sign}^\gamma(x) = |x|^\gamma \text{sign}(x) \), so that \( \text{sign}^0(x) = \text{sign}(x) \).

2 | PRELIMINARIES AND PROBLEM FORMULATION
In this section, some preliminaries on fractional calculus and Mittag-leffler functions are recalled. Then, the considered control problem is formulated.

2.1 | Preliminaries on fractional calculus
Let us recall some definitions concerning fractional order derivatives. For any real number \( \alpha > 0 \) (namely, the derivative order), the Riemann-Liouville fractional derivative for a function \( \Psi : [a, \infty) \rightarrow \mathbb{R} \) is given by\[42,43\]

\[
\mathcal{RL}_a D^\alpha \Psi(t) = \frac{1}{\Gamma(Y - \alpha)} \frac{d^Y}{dt^Y} \int_a^t \frac{\Psi(\tau)}{(t-\tau)^{Y-\alpha+1}} d\tau,
\]

where \( Y \in \mathbb{N}^* \) is such that \((Y - 1) < \alpha < Y\) and \( \Gamma(\cdot) \) is the Gamma function expressed as

\[
\Gamma(K) = \int_0^\infty e^{-t} t^{K-1} dt.
\]

Furthermore, for any real number \( \alpha > 0 \), the Caputo fractional derivative (CFD) for a function \( \Psi : [a, \infty) \rightarrow \mathbb{R} \) is given by\[43,44\]

\[
\mathcal{C}_a D^\alpha \Psi(t) = \frac{1}{\Gamma(a-Y)} \int_a^t \frac{\Psi^{(Y)}(\tau)}{(t-\tau)^{a-Y+1}} d\tau.
\]

Some important properties are recalled hereafter.
Property 1. For any real numbers $\alpha \geq \lambda \geq 0$, the CFD for a function $\Psi : [t_0, \infty) \to \mathbb{R}$ satisfies
\[
C \int_{t_0}^{t} D_{t}^{\alpha} D_{t}^{-\lambda} \Psi (t) \, dt = C \int_{t_0}^{t} D_{t}^{\alpha - \lambda} \Psi (t) \, dt.
\] (4)

Property 2. Let $0 < \alpha < 1$ and $\Psi : [t_0, \infty) \to \mathbb{R}$, then the following equality holds:
\[
C D_{t}^{1-\alpha} C D_{t}^{\alpha} \Psi (t) = C D_{t}^{1-\alpha} D_{t}^{1-\alpha \alpha} \Psi (t) = \Psi (t).
\] (5)

In the following, the operator $C D_{t}^{\alpha}$ will be replaced by $D_{t}^{\alpha}$ throughout this paper.

2.2 Mittag-Leffler type functions
The Mittag-Leffler function can be defined as:
\[
E_{\xi}(X) = \sum_{\rho = 0}^{\infty} \frac{X^\rho}{\Gamma(\rho \xi + 1)},
\] (6)
with $\rho$ being a strictly positive constant. When two arguments are taken into account, the Mittag-Leffler function becomes
\[
E_{\xi_1, \xi_2}(X) = \sum_{\rho = 0}^{\infty} \frac{X^\rho}{\Gamma(\rho \xi_1 + \xi_2)},
\] (7)
with $\xi_1, \xi_2 > 0$. Hence, one has $E_{\xi}(X) = E_{\xi_1,1}(X)$ and $E_{1,1}(X) = e^X$.

2.3 Problem statement
Consider the following nonlinear system
\[
\begin{cases}
\dot{Z}_1 = Z_2 \\
\dot{Z}_2 = Z_3 \\
\vdots \\
\dot{Z}_{n-1} = Z_n \\
\dot{Z}_n = F(Z) + G(Z)U + D(Z, t),
\end{cases}
\] (8)
where the state vector is $Z = [Z_1, Z_2, ..., Z_n]^T \in \mathbb{R}^n$ and the control input is $U \in \mathbb{R}$. Furthermore, $F(Z)$ and $G(Z) \neq 0$ are two known nonlinear functions, while $D(Z, t)$ represents uncertainties and external disturbances.

Assumption 1. It is assumed that $D(Z, t) < Y_T$ and $\dot{D}(Z, t) < Y_d$ where $Y_T > 0$ and $Y_d > 0$.

The control objective is to design a robust controller which guarantees $\text{Ft}$ stability of the origin of the closed-loop system (8) without knowing the upper bound of the disturbances. The following lemmas will be useful to derive the main results.

Lemma 1. Consider the sliding variable
\[
S = \dot{Z}_n + \kappa_n \text{sign} \left( Z_n \right) |Z_n|^{\mu_n} + ... + \kappa_1 \text{sign} \left( Z_1 \right) |Z_1|^{\mu_1},
\] (9)
where $\mu_j$ and $\kappa_j (j = 1, 2, ..., n)$ are positive constants such that the polynomial $p^\mu + \kappa_n p^{\mu_n} + ... + \kappa_2 p + \kappa_1$ is Hurwitz and
\[
\begin{align*}
\mu_j &= \mu_j, \\
\mu_{j-1} &= \frac{\mu_j \mu_{j+1}}{2\mu_{j+1} - \mu_j}, & j = 1, 2, ..., n, \quad \forall n \geq 2
\end{align*}
\] (10)
with $\mu_{n+1} = 1$, $\mu_n = \mu$, $\mu \in (1 - c, 1)$ and $c \in (0, 1)$. Once the sliding mode is established (i.e., $S = 0$), the system state converges to zero in $\text{Ft}$.

Theorem 1. (Refer to Reference) If the sliding-mode surface $S$ is selected as (9) and the control is built as follows (11), the nonlinear system (8) will approach $S = 0$ in finite time and then converge to zero along $S = 0$ in $\text{Ft}$.
\[
U = \frac{1}{G(Z)} \left( U_0 + U_1 \right),
\] (11)
The proposed FORITSM control law

\[ U_0 = -P(Z) - \kappa_n \text{sign} (Z_n) |Z_n|^{\mu_n} - ... - \kappa_1 \text{sign} (Z_1) |Z_1|^{\mu_1} \]  

\[ \dot{U}_1 + \mathcal{T} U_1 = \zeta, \]

\[ \zeta = - (Y_d + Y_T + \zeta_0) \text{sign}(\sigma). \]  

where \( Y_d, Y_T, \zeta \) are positive parameters. It has been proved that when \( S = 0 \), the system states converge to zero in finite time (referred to as \( t_S \)).

**Lemma 2** (\cite{Labbadi2023}). Consider the first-order nonlinear differential equation

\[ \dot{Y} + \Lambda \text{sign} (Y)^a = 0, \]  

with \( \Lambda > 0, 0 < a < 1 \). Then, \( Y \) converges to zero in a finite-time given by

\[ t_f = \frac{|Y(0)|^{1-a}}{\Lambda(1-a)}. \]  

### 3 THE PROPOSED FORITSM CONTROL LAW

To design the proposed robust controller, let us consider the following fractional-order integral terminal sliding variable, i.e.,

\[ \sigma = S + \Lambda D^{\beta \gamma} S_I \]  

with \( \Lambda > 0, 0 < \beta < 1 \). The sliding variable \( S \) is given in (10) and \( S_I \) can be designed as:

\[ D^{\beta} S_I = \text{sign}(S) |S|^\alpha, \]  

with initial value

\[ S_I(0) = -\frac{1}{\Lambda} D^{1-\beta} S(0). \]  

From Eqs. (16)-(18), one can easily see that \( \sigma(0) = 0 \). Hence, the reaching phase to the sliding surface \( \sigma = 0 \) is removed.

**Remark 1.** The proposed recursive form terminal sliding variable (16) combines two sliding variables (i.e., (9) and (17)). If an appropriate control input is designed such that the sliding mode is established (i.e., \( \sigma = 0 \), the system trajectories will be constrained to the sliding surface \( \sigma = 0 \), and then to the origin in FnT. Because of the integral initial condition in (18), the RP is cancelled in comparison to conventional TSM control. Moreover, compared to integral HOMS control, only two layers of sliding manifolds are adopted in the integral TSM, which is simpler for practical implementations. In addition, the proposed sliding manifold offers exact degree to increase the performance tracking of the full nonlinear system.

Compute now the time derivative of \( \sigma \), i.e.,

\[ \dot{\sigma} = \dot{S} + \Lambda D^{\beta \gamma} S_I \]

\[ = \ddot{Z}_n + \kappa_n \mu_n |Z_n|^{\mu_n-1} \dot{Z}_n + ... + \kappa_n \mu_n |Z_n|^{\mu_n-1} \dot{Z}_1 + \Lambda D^{\beta \gamma} S_I. \]  

**Theorem 2.** Given the nonlinear system (8), consider the sliding variable (16) and the following controller

\[ U = G(Z)^{-1} (U_0 + U_1) \]  

\[ U_0 = -P(Z) - \kappa_n \text{sign} (Z_n) |Z_n|^{\mu_n} - ... - \kappa_1 \text{sign} (Z_1) |Z_1|^{\mu_1} - \Lambda D^{\beta \gamma} S_I \]  

\[ D^{\beta \gamma} U_1 + \mathcal{T} U_1 = \zeta_I, \]

\[ \zeta_I = - (Y_d + Y_T + \zeta_0) D^{k-1} \text{sign}(\sigma) - K_f D^{k-1} \sigma, \]

with \( \kappa \) being positive constants, \( Y_d, Y_T, \zeta_0 \) being positive constants, \( \lambda \) being a fractional operator, and the two constants \( Y_d \) and \( Y_T \) chosen such that \( Y_T > T \delta \). Then, the trajectories of (8), constrained to \( \sigma = 0 \), will converge to zero in a FnT and the settling time satisfying \( T_{FnT} \leq t_S + t_s + t^c \).

**Proof.** Making reference to system (8), the sliding variable (16) can be expressed as

\[ \sigma = \ddot{Z}_n + \kappa_n \text{sign} (Z_n) |Z_n|^{\mu_n} + ... + \kappa_1 \text{sign} (Z_1) |Z_1|^{\mu_1} + \Lambda D^{\beta \gamma} S_I. \]  

\[ = P(Z) + G(Z) U + D(Z, t) + \kappa_n \text{sign} (Z_n) |Z_n|^{\mu_n} + ... + \kappa_1 \text{sign} (Z_1) |Z_1|^{\mu_1} + \Lambda D^{\beta \gamma} S_I. \]
Replacing the control $u(t)$ into equation (23) yields
\[
\sigma = P(Z) + U_0 + U_1 + D(Z) + \kappa_n \text{sign} (Z_n) |Z_n| \mu_n + \cdots + \kappa_1 \text{sign} (Z_1) |Z_1| \mu_1 + \Lambda D^{\delta-1} S_f
\]
\[
= U_1 + D(Z).
\] (24)

The FO switching law can be written as
\[
D^\delta U_1 + T U_1 = - (Y_d + Y_T + \zeta_0) D^{\delta-1} \text{sign}(\sigma) - K_f D^{\delta-1} \sigma
\]
\[
= -D^{\delta-1} \left[ (Y_d + Y_T + \zeta_0) \text{sign}(\sigma) - K_f \sigma \right].
\] (25)

After simple calculation, one has
\[
\dot{U}_1 + T D^{1-\delta} U_1 = - (Y_d + Y_T + \zeta_0) \text{sign}(\sigma) - K_f \sigma.
\] (27)

Since the Laplace transform of Eq. (27) is
\[
sU_1(s) - U_1(0) + T s^{1-\delta} U_1(s) - T s^{-\delta} U_1(0) = \zeta_f(s),
\] (28)

with non negative constant $U_1(0) = U_1(0, \sigma(0))$, then Eq. (28) can be defined as
\[
U_1(s) = \frac{\zeta_f(s) s^{-\delta} + U_1(0) s^{-\delta} + s^{-1-\delta} U_1(0)}{1 + T s^{-\delta}}
\] (29)

The unique solution of (29) arises from the uniqueness and existence theorem of fractional equations and the properties of inverse Laplace transform since $U_1(t, \sigma)$ is locally Lipschitz with respect to $\sigma$. The solution of (25) is given by:
\[
U_1(t) = U_1(0) T^{-\delta} E_{-\lambda, -\delta+1} (-T t^{-\delta}) + U_1(0) E_{-\lambda} (-T t^{-\delta}) + \int_0^t (t - \tau)^{-\delta} E_{-\lambda, -\delta+1} \left(-T (t - \tau)^{-\delta}\right) \zeta_f(\tau) d\tau,
\] (30)

where $E_{-\lambda} (-T t^{\delta})$ and $E_{-\lambda, -\delta+1} (-T t^{\delta})$ are Mittag-Leffler functions.

Using the condition $Y_T > T T$ and from (24) and (29), under the condition $U_1(0) = 0$, one obtains $Y_T \geq T$, $Y_d \geq T$, and $|U_1|_{\text{max}} \geq T |U_1(t)|$, which in turn implies $T |U_1(t)| \leq Y_T$. The fractional derivative of the terminal sliding manifold (24) is
\[
D^\delta \sigma = D^\delta D(Z) + D^\delta U_1
\]
\[
= D^\delta D(Z) + D^\delta U_1 + T U_1 - T U_1
\]
\[
= D^\delta D(Z) + \zeta_f - T U_1
\]
\[
= D^\delta D(Z) - D^{\delta-1} \left[ (Y_d + Y_T + \zeta_0) \text{sign}(\sigma) - K_f \sigma \right] - T U_1.
\] (34)

Consider now the Lyapunov function and its time-derivative as $V = \frac{1}{2} \sigma^2$ and $\dot{V} = \sigma \dot{\sigma} = \sigma D^{1-\delta}(D^\delta \sigma)$. One gets
\[
\dot{V} = \sigma D^{1-\delta} \{ D^\delta D(Z) - D^{\delta-1} \left[ (Y_d + Y_T + \zeta_0) \text{sign}(\sigma) - K_f \sigma \right] - T U_1 \}
\]
\[
= \sigma \{ D(Z) - \left[ (Y_d + Y_T + \zeta_0) \text{sign}(\sigma) - K_f \sigma \right] - T D^{\delta-1} U_1 \}
\]
\[
= \dot{D}(Z) \sigma - (Y_d + Y_T + \zeta_0) |\sigma| - K_f \sigma^2 - T D^{\delta-1} U_1
\]
\[
\leq |D(Z)| |\sigma| - Y_d |\sigma| + |T D^{\delta-1} U_1 \sigma - Y_T |\sigma| - \zeta_0 |\sigma| - K_f \sigma^2
\] (38)

According to the Assumption (1) and exploiting (35), one gets
\[
\dot{V} = \sigma \dot{\sigma} \leq -\zeta_0 |\sigma| - K_f \sigma^2.
\] (39)

To demonstrate the finite-time stability, (39) can be rewritten as
\[
\dot{V} \leq -2 K_f V - \sqrt{2 \zeta_0 V}. (40)
\]

Dividing (40) by $V^{\frac{3}{2}}$, one obtains
\[
dt \leq - \frac{V^{-\frac{1}{2}}}{2 K_f V^{\frac{1}{2}} + \sqrt{2 \zeta_0}} dV.
\] (41)
By integrating (41) from \( t_0 \) to \( t_c \) and after a simple calculation, it yields

\[
\begin{align*}
t_c - t_0 & \leq - \int_{V(t_0)}^{0} \frac{V^{-\frac{1}{2}}}{2K_f V^\frac{1}{2} + \sqrt{2\varsigma_0}} dV \\
& = \frac{1}{K_f} \ln \frac{2K_f V^\frac{1}{2}(t_0) + \sqrt{2\varsigma_0}}{2K_f V^\frac{1}{2}(t_0) + \sqrt{2\varsigma_0}}.
\end{align*}
\]

(42)

On the other hand, this implies that, in a finite amount of time, one has \( \sigma = 0 \), and the trajectories of system (49) will converge to zero in \( \text{FnT} \) as well, under \( \sigma = 0 \). In fact, if \( \sigma = 0 \) holds in (16), the sliding variable will converge to zero in a \( \text{FnT} \) according to Lemma 2, i.e.,

\[
\begin{align*}
\sigma = & \, S + \Lambda D^{\beta-1} S_{t_\beta} = 0 \\
D^{\beta} S_{t_\beta} = & \, \text{sig}(S)^a.
\end{align*}
\]

(44)

Hence, one has

\[
\begin{align*}
D^{\beta} S_{t_\beta} = & \, \text{sig}(-\Lambda D^{\beta-1} S_{t_\beta})^a \\
= & \, -\Lambda^a D^{\beta-1} \text{sig}^a(S_{t_\beta}),
\end{align*}
\]

which, after a simple calculation, implies

\[
\dot{S}_{t_\beta} = -\Lambda^a \text{sig}^a(S_{t_\beta}).
\]

(45)

Making reference to Lemma [2], the convergence time \( t_s \) is given by

\[
t_s = \frac{|\sigma(0)|^{1-a}}{\Lambda(1-a)}.
\]

(47)

Finally, from Theorem 1 “\( t_S \)”, (43) and (46), the settling time can be estimated as \( \text{T}_{\text{FnT}} \leq t_s + t_s + t_c. \)

\[\Box\]

**Remark 2.** The control signal (22) is the same as a fractional-order high-pass filter (FOHPF), with \( \epsilon(t) \) as the input and \( U_1(t) \) as the filter’s output. The fractional-order filter’s Laplace transfer function (22) is given by

\[
\frac{U_1(t)}{\epsilon(t)} = \frac{s^{\lambda-1}}{s^\lambda + \mathcal{T}},
\]

where \( \mathcal{T} \) is the FOHPF’s bandwidth, while \( U_1(t) \) in (20) is the output of the FOHPF (22) which is softened to be a smooth signal by the switch function, despite the fact that \( \epsilon(t) \) is non-smooth due to the switching function (22).

**Remark 3.** They are two advantages of the proposed of the fractional-order command filter compared to the integer-order command filter. First, for the recursive sliding manifold with given fractional order derivative and gain following the design guidelines. That is, the closed-loop system (8) could be finite-time stable with more degree of freedom. Second, the fundamental distinction between the proposed FO command filter and their integer filter, where it is shown that the parameter adds an extra degree of parameter degree of freedom. With the use of this parameter \( \lambda \), the suggested technique may be able to better balance various conflict performance standards.

**Remark 4.** The disadvantage of the strategies proposed in (9), (12), (10) is that the reaching phase is still present. The reaching phase is instead removed in our method due to the proposed recursive fractional-order integral terminal sliding manifold, and the system begins to move on the sliding surface since the initial time instant. Moreover, the proposal exhibits certain noteworthy characteristics with respect to existing methods in (9), (12), (10) which are outlined as follows:

- First, for the existing nonsingular terminal sliding manifold (12), the designed surface variables following the non-recursive manner can only admit an existence condition for \( \text{FnT} \) stability. Still, in the present paper, the proposed controller ensures finite-time stability without an existing condition and the settling time satisfying \( \text{T}_{\text{FnT}} \leq t_s + t_s + t_c. \)

- It can be seen from the existing works (12), (10) that the proposed FORITSM offers two additional degrees of freedom, due to the designed FO filter and the FO cursive integral sliding manifold.
4 APPLICATION TO TRACKING CONTROL FOR A QUADROTOR UAV

In this section, the proposed control approach is applied to the dynamics of a quadrotor UAV, showing its applicability in a practical case.

4.1 Modelling and tracking control problem

Consider a quadrotor system captured by the following equations

\[ \dot{\psi} = \theta \psi \left( J_{yy} - J_{zz} \right) - \frac{I_{rr}}{J_{xx}} \Omega_0 \phi - \frac{\theta_0}{J_{xx}} \phi^2 + \frac{1}{J_{xx}} \tau_\phi + D_\phi \]

\[ \ddot{\theta} = \dot{\phi} \left( J_{zz} - J_{xx} \right) + \frac{I_{rr}}{J_{yy}} \Omega_0 \dot{\phi} - \frac{\theta_0}{J_{yy}} \dot{\phi}^2 + \frac{1}{J_{yy}} \tau_\theta + D_\theta \]

\[ \ddot{\psi} = \phi \theta \left( J_{xx} - J_{yy} \right) + \frac{\theta_0}{J_{zz}} \psi^2 + \frac{1}{J_{zz}} \tau_\psi + D_\psi \]

\[ \ddot{x} = \frac{g}{m} x + (\cos \phi \sin \theta \cos \psi + \sin \phi \sin \psi) \frac{T}{m} + D_x \]

\[ \ddot{y} = \frac{g}{m} y + (\cos \phi \sin \theta \sin \psi - \sin \phi \cos \psi) \frac{T}{m} + D_y \]

\[ \ddot{z} = \frac{g}{m} z - g + (\cos \phi \cos \theta) \frac{T}{m} + D_z, \]

where the Euler angles of the quadrotor are expressed as \( \Psi_\eta = [\phi \ \theta \ \psi]^T \), and \( \dot{\Psi}_\eta = [\dot{\phi} \ \dot{\theta} \ \dot{\psi}]^T \) are the angular rates. As shown in Fig. (1), the absolute position of the quadrotor is \( \Psi_q = [x \ y \ z]^T \), and \( \dot{\Psi}_q = [\dot{x} \ \dot{y} \ \dot{z}]^T \) represents the linear velocity, where \( J_{xx}, J_{yy}, \) and \( J_{zz} \) are inertia moments of the vehicle around \( b_x, b_y, b_z \) axes, \( m \) is the mass of the body, \( D_\phi, D_\theta, D_\psi, D_x, D_y, \) and \( D_z \) denote the external disturbances, and \( g \) is the gravitational acceleration. Moreover, \( \theta_i |_{x,y,z,\phi,\theta,\psi} \) are drag coefficients, and \( [T \ \tau_\phi \ \tau_\theta \ \tau_\psi]^T \) are the control inputs. In order to generate the total thrust \( T \) and the tilting angles \( (\phi_d, \theta_d) \), the virtual control input can be defined as follows

\[ P_x = (\cos \phi \sin \theta \cos \psi + \sin \phi \sin \psi) \frac{T}{m} \]

\[ P_y = (\cos \phi \sin \theta \sin \psi - \sin \phi \cos \psi) \frac{T}{m} \]

\[ P_z = -g + (\cos \phi \cos \theta) \frac{T}{m} \]

We are now in a position to formulate the considered tracking control problem. Specifically, the control objective is to design a FORITSM control for the system (49) in order to make the quadrotor follow a reference trajectory. In this context, the virtual signal \( P_i = [P_x, P_y, P_z]^T \) will be designed in order to generate the total thrust \( T \), the tilting angles \( (\phi_d, \theta_d) \) for the outer loop, and the torque controls \( (\tau_\phi, \tau_\theta, \tau_\psi) \), as shown in Fig. (2).
4.2 FORITSM control design for the quadrotor

Let us define the tracking errors and their derivatives for the quadrotor position as follows

\[ e_x = x - x_d, \quad \dot{e}_x = \dot{x} - \dot{x}_d \] (53)

and

\[ \ddot{e}_x = \ddot{x} - \ddot{x}_d, \quad \dot{e}_z = \dot{z} - \dot{z}_d \] (54)

Similarly, the tracking errors and their derivatives are defined for the attitude as follows

\[ e_\phi = \phi - \phi_d, \quad \dot{e}_\phi = \dot{\phi} - \dot{\phi}_d \]

\[ e_\theta = \theta - \theta_d, \quad \dot{e}_\theta = \dot{\theta} - \dot{\theta}_d \]

\[ e_\psi = \psi - \psi_d, \quad \dot{e}_\psi = \dot{\psi} - \dot{\psi}_d \] (55)

and

\[ \ddot{e}_\phi = \ddot{\phi} - \ddot{\phi}_d, \quad \ddot{e}_\theta = \ddot{\theta} - \ddot{\theta}_d, \quad \ddot{e}_\psi = \ddot{\psi} - \ddot{\psi}_d \] (56)

Now, in order to design the proposed FORITSM control, the fast nonsingular terminal sliding manifolds for the position need to be defined as

\[ S_x = \ddot{e}_x + \kappa_x \text{sign}(\dot{e}_x) \left| \dot{e}_x \right|^{\mu_x} + \kappa_{x1} \text{sign}(e_x) \left| e_x \right|^{\mu_{x1}} \] (57)

\[ S_y = \ddot{e}_y + \kappa_y \text{sign}(\dot{e}_y) \left| \dot{e}_y \right|^{\mu_y} + \kappa_{y1} \text{sign}(e_y) \left| e_y \right|^{\mu_{y1}} \] (58)

\[ S_z = \ddot{e}_z + \kappa_z \text{sign}(\dot{e}_z) \left| \dot{e}_z \right|^{\mu_z} + \kappa_{z1} \text{sign}(e_z) \left| e_z \right|^{\mu_{z1}} \] (59)

The fast nonsingular terminal sliding manifolds for the attitude are instead given by

\[ S_\phi = \ddot{e}_\phi + \kappa_\phi \text{sign}(\dot{e}_\phi) \left| \dot{e}_\phi \right|^{\mu_\phi} + \kappa_{\phi1} \text{sign}(e_\phi) \left| e_\phi \right|^{\mu_{\phi1}} \] (60)

\[ S_\theta = \ddot{e}_\theta + \kappa_\theta \text{sign}(\dot{e}_\theta) \left| \dot{e}_\theta \right|^{\mu_\theta} + \kappa_{\theta1} \text{sign}(e_\theta) \left| e_\theta \right|^{\mu_{\theta1}} \] (61)

\[ S_\psi = \ddot{e}_\psi + \kappa_\psi \text{sign}(\dot{e}_\psi) \left| \dot{e}_\psi \right|^{\mu_\psi} + \kappa_{\psi1} \text{sign}(e_\psi) \left| e_\psi \right|^{\mu_{\psi1}} \] (62)

The control parameters \( \mu_{i1} \) and \( \mu_{i2} \) for \( i = x, y, z, \phi, \theta, \psi \) are selected according to Lemma [1] while \( \kappa_{i1} \) and \( \kappa_{i2} \) are positive coefficients.

The fractional-order integral terminal sliding manifolds for the position and attitude are respectively

\[ \sigma_x = S_x + \lambda_x D^{\beta_x-1} S_{1\beta_x}, \quad \sigma_y = S_y + \lambda_y D^{\beta_y-1} S_{1\beta_y}, \quad \sigma_z = S_z + \lambda_z D^{\beta_z-1} S_{1\beta_z}, \] (63)

and

\[ \sigma_\phi = S_\phi + \lambda_\phi D^{\beta_\phi-1} S_{1\beta_\phi}, \quad \sigma_\theta = S_\theta + \lambda_\theta D^{\beta_\theta-1} S_{1\beta_\theta}, \quad \sigma_\psi = S_\psi + \lambda_\psi D^{\beta_\psi-1} S_{1\beta_\psi}, \] (64)

where \( \lambda_i \) are positive coefficients and \( S_j \) as in (57) and (62), while \( S_{1\beta_i} \) can be designed as

\[ D^{\beta_i} S_{1\beta_i} = \text{sign} \left( S_j \right)^{\alpha_i}, \quad D^{\beta_i} S_{1\beta_i} = \text{sign} \left( S_j \right)^{\alpha_i}, \quad D^{\beta_i} S_{1\beta_i} = \text{sign} \left( S_j \right)^{\alpha_i}, \] (65)

and

\[ D^{\beta_i} S_{1\beta_i} = \text{sign} \left( S_j \right)^{\alpha_i}, \quad D^{\beta_i} S_{1\beta_i} = \text{sign} \left( S_j \right)^{\alpha_i}, \quad D^{\beta_i} S_{1\beta_i} = \text{sign} \left( S_j \right)^{\alpha_i}. \] (66)
Assumption 2. We assume the disturbance $D_i$ is bounded and its derivative $D_{i}'$ is also bounded. Both disturbance and its derivative satisfy the following conditions: $|D_i| < Y_{d_i}$ and $|D_{i}'| < Y_{d_i}$. Keep in mind that this assumption holds true in real-world scenarios. As an illustration, the load torque may hang when a cutting tool or end mill of a CNC machine tool cuts a work-piece as the cutting thickness increases, but the change rate of the load torque is always constrained.

Theorem 3. Given the quadrotor dynamics (49), controlled via the FORITSM control laws (67)-(84), that is, for the $x$-subsystem

$$P_x = (P_{x0} + P_{x1})$$

$$P_{x0} = -\frac{\theta}{m} \dot{\bar{x}} - \kappa_{x2}\text{sign} (\bar{e}_x) \| \bar{e}_x \|^\mu_{x2} - \kappa_{x1}\text{sign} (\bar{e}_x) \| \bar{e}_x \|^\mu_{x1} - \Lambda_x D^\beta_x S_{I\beta_x}$$

$$D^{\delta_x} P_{x1} + T_x P_{x1} = \xi_x$$

$$\xi_x = -(Y_{dx} + Y_{Tx} + \xi_{x0}) D^{\delta_x-1}\text{sign}(\sigma_x) - K_{fx} D^{\delta_x-1} \sigma_x,$$

for the $y$-subsystem

$$P_y = (P_{y0} + P_{y1})$$

$$P_{y0} = -\frac{\theta}{m} \dot{\bar{y}} - \kappa_{y2}\text{sign} (\bar{e}_y) \| \bar{e}_y \|^\mu_{y2} - \kappa_{y1}\text{sign} (\bar{e}_y) \| \bar{e}_y \|^\mu_{y1} - \Lambda_y D^\beta_y S_{I\beta_y}$$

$$D^{\delta_y} P_{y1} + T_y P_{y1} = \xi_y$$

$$\xi_y = -(Y_{dy} + Y_{Ty} + \xi_{y0}) D^{\delta_y-1}\text{sign}(\sigma_y) - K_{fy} D^{\delta_y-1} \sigma_y,$$

for the $z$-subsystem

$$P_z = (P_{z0} + P_{z1})$$

$$P_{z0} = -\frac{\theta}{m} \dot{z} + g - \kappa_{z2}\text{sign} (\bar{e}_z) \| \bar{e}_z \|^\mu_{z2} - \kappa_{z1}\text{sign} (\bar{e}_z) \| \bar{e}_z \|^\mu_{z1} - \Lambda_z D^\beta_z S_{I\beta_z}$$

$$D^{\delta_z} P_{z1} + T_z P_{z1} = \xi_z$$

$$\xi_z = -(Y_{dz} + Y_{Tz} + \xi_{z0}) D^{\delta_z-1}\text{sign}(\sigma_z) - K_{fz} D^{\delta_z-1} \sigma_z,$$

for the $\phi$-subsystem

$$\tau_\phi = J_{XX} (\tau_{\phi0} + \tau_{\phi1})$$

$$\tau_{\phi0} = -\{\phi \frac{(J_{YY} - J_{XX})}{J_{XX}} \Omega_y \dot{\phi} - \frac{\theta}{J_{XX}} \dot{\phi}^2 \} - \kappa_{\phi2}\text{sign} (\bar{e}_\phi) \| \bar{e}_\phi \|^\mu_{\phi2} - \kappa_{\phi1}\text{sign} (\bar{e}_\phi) \| \bar{e}_\phi \|^\mu_{\phi1} - \Lambda_\phi D^\beta_\phi S_{I\beta_\phi}$$

$$D^{\delta_\phi} \tau_{\phi1} + T_\phi \tau_{\phi1} = \xi_\phi,$$

$$\xi_\phi = -(Y_{d\phi} + Y_{T\phi} + \xi_{\phi0}) D^{\delta_\phi-1}\text{sign}(\sigma_\phi) - K_{f\phi} D^{\delta_\phi-1} \sigma_\phi,$$

for the $\theta$-subsystem

$$\tau_\theta = J_{YY} (\tau_{\theta0} + \tau_{\theta1})$$

$$\tau_{\theta0} = -\{\phi \frac{(J_{ZZ} - J_{XX})}{J_{YY}} \Omega_y \dot{\phi} - \frac{\theta}{J_{YY}} \dot{\phi}^2 \} - \kappa_{\theta2}\text{sign} (\bar{e}_\theta) \| \bar{e}_\theta \|^\mu_{\theta2} - \kappa_{\theta1}\text{sign} (\bar{e}_\theta) \| \bar{e}_\theta \|^\mu_{\theta1} - \Lambda_\theta D^\beta_\theta S_{I\beta_\theta}$$

$$D^{\delta_\theta} \tau_{\theta1} + T_\theta \tau_{\theta1} = \xi_\theta,$$

$$\xi_\theta = -(Y_{d\theta} + Y_{T\theta} + \xi_{\theta0}) D^{\delta_\theta-1}\text{sign}(\sigma_\theta) - K_{f\theta} D^{\delta_\theta-1} \sigma_\theta,$$

and for the $\psi$-subsystem

$$\tau_\psi = J_{ZZ} (\tau_{\psi0} + \tau_{\psi1})$$

$$\tau_{\psi0} = -\{\phi \frac{(J_{ZZ} - J_{YY})}{J_{ZZ}} \Omega_y \dot{\phi} - \frac{\theta}{J_{ZZ}} \dot{\psi}^2 \} - \kappa_{\psi2}\text{sign} (\bar{e}_\psi) \| \bar{e}_\psi \|^\mu_{\psi2} - \kappa_{\psi1}\text{sign} (\bar{e}_\psi) \| \bar{e}_\psi \|^\mu_{\psi1} - \Lambda_\psi D^\beta_\psi S_{I\beta_\psi}$$

$$D^{\delta_\psi} \tau_{\psi1} + T_\psi \tau_{\psi1} = \xi_\psi,$$

$$\xi_\psi = -(Y_{d\psi} + Y_{T\psi} + \xi_{\psi0}) D^{\delta_\psi-1}\text{sign}(\sigma_\psi) - K_{f\psi} D^{\delta_\psi-1} \sigma_\psi,$$

where $\kappa_1, \kappa_2 > 0$, $Y_{d_i}$, $Y_{T_i}$, and $\xi_{i0}$ are positive constants, $\lambda_i$ is fractional operator, and $Y_{d_i}$ and $Y_{T_i}$ are two constants, if $Y_{T_i} > T_i \delta_i$, then $\sigma_x, \sigma_y, \sigma_z, \sigma_\phi, \sigma_\theta$, and $\sigma_\psi$ are zeroed in a finite time. Moreover, the position and attitude dynamics in (49) are
regulated to their references in a finite time, constrained to the sliding mode on \( \sigma_x = \sigma_y = \sigma_z = \sigma_\phi = \sigma_\theta = \sigma_\psi = 0 \). The global settling time for quadrotor position and attitude satisfying \( T_{GFT} \leq T_{xFT} + T_{yFT} + T_{zFT} + T_{\phi FT} + T_{\theta FT} + T_{\psi FT} \).

**Proof.** Taking into account the sliding manifolds in (57), (62), and substituting the proposed control laws (67)-(84) to (63), (64), one has

\[
\sigma_x = P_{x1} + D_x, \quad \sigma_y = P_{y1} + D_y, \quad \sigma_z = P_{z1} + D_z, \quad (85)
\]

and

\[
\sigma_\phi = \tau_{\phi 1} + D_\phi, \quad \sigma_\theta = \tau_{\theta 1} + D_\theta, \quad \sigma_\psi = \tau_{\psi 1} + D_\psi. \quad (86)
\]

Using the results of the Theorem 2, the solutions of the control inputs (69), (72), (75), (78), (81), and (84) are

\[
P_{y1}(t) = P_{x1}(0)E^{-\lambda , -\lambda_{y1}}( - \tau_{y} t^{-\lambda } ) + P_{x1}(0)E^{-\lambda , -\lambda_{y1}}( - \tau_{x} t^{-\lambda } ) \int_{0}^{t} (t - \tau)^{-\lambda} E^{-\lambda , -\lambda_{y1}}( - \tau_{x} (t - \tau)^{-\lambda} ) \xi_x(\tau) d\tau \quad (87)
\]

\[
P_{z1}(t) = P_{x1}(0)E^{-\lambda , -\lambda_{z1}}( - \tau_{z} t^{-\lambda } ) + P_{x1}(0)E^{-\lambda , -\lambda_{z1}}( - \tau_{x} t^{-\lambda } ) \int_{0}^{t} (t - \tau)^{-\lambda} E^{-\lambda , -\lambda_{z1}}( - \tau_{x} (t - \tau)^{-\lambda} ) \xi_z(\tau) d\tau \quad (88)
\]

\[
P_{\phi 1}(t) = \tau_{\phi 1}(0)E^{-\lambda , -\lambda_{\phi 1}}( - \tau_{\phi} t^{-\lambda } ) + P_{x1}(0)E^{-\lambda , -\lambda_{\phi 1}}( - \tau_{\phi} t^{-\lambda} ) \int_{0}^{t} (t - \tau)^{-\lambda} E^{-\lambda , -\lambda_{\phi 1}}( - \tau_{\phi} (t - \tau)^{-\lambda} ) \xi_\phi(\tau) d\tau \quad (89)
\]

\[
P_{\theta 1}(t) = \tau_{\theta 1}(0)E^{-\lambda , -\lambda_{\theta 1}}( - \tau_{\theta} t^{-\lambda } ) + P_{x1}(0)E^{-\lambda , -\lambda_{\theta 1}}( - \tau_{\phi} t^{-\lambda} ) \int_{0}^{t} (t - \tau)^{-\lambda} E^{-\lambda , -\lambda_{\theta 1}}( - \tau_{\theta} (t - \tau)^{-\lambda} ) \xi_\theta(\tau) d\tau \quad (90)
\]

\[
P_{\psi 1}(t) = \tau_{\psi 1}(0)E^{-\lambda , -\lambda_{\psi 1}}( - \tau_{\psi} t^{-\lambda } ) + P_{x1}(0)E^{-\lambda , -\lambda_{\psi 1}}( - \tau_{\psi} t^{-\lambda} ) \int_{0}^{t} (t - \tau)^{-\lambda} E^{-\lambda , -\lambda_{\psi 1}}( - \tau_{\psi} (t - \tau)^{-\lambda} ) \xi_\psi(\tau) d\tau \quad (91)
\]

Using the condition \( Y_{Ti} > T_{i} \delta_{i} \) and from (24) and (57), (92), under the condition \( P_{x}(0) = P_{y}(0) = P_{z}(0) = \tau_{\phi}(0) = \tau_{\theta}(0) = \tau_{\psi} = 0 \) one obtains \( Y_{Ti} \geq T_{i} \), \( Y_{di} \geq T_{i} \), and \( Y_{Ti} \geq T_{i} \) \( \max \) \( Y_{Ti} \geq T_{i} \), i.e.,

\[
T_{i} \left| P_{x1}, P_{y1}, P_{z1}, \tau_{\phi 1}, \tau_{\theta 1}, \tau_{\psi 1} \right| \leq Y_{Ti} .
\]

Consider now the global Lyapunov function for overall quadrotor system \( V = \frac{1}{2} \left[ \sigma_x^2 + \sigma_y^2 + \sigma_z^2 + \sigma_\phi^2 + \sigma_\theta^2 + \sigma_\psi^2 \right] \) The FO derivative of terminal sliding manifold is

\[
D^\lambda \sigma_i = D^\lambda D_i + D^\lambda \Gamma \quad (93)
\]

\[
= D^\lambda D_i + D^\lambda \Gamma - T_i \Gamma \quad (94)
\]

\[
= D^\lambda D_i + \zeta_i - T_i \Gamma \quad (95)
\]

\[
= D^\lambda D_i - D_i^{-1} \left[ \left( Y_{di} + Y_{Ti} + \zeta_{0} \right) \text{sign}(\sigma_i) - K_f \sigma_i \right] - T_i \Gamma . \quad (96)
\]

with \( \Gamma \) representing the input controls \( P_x, P_y, P_z, \tau_\phi, \tau_\theta, \tau_\psi \). Hence,

\[
\sigma_i \dot{\sigma}_i = \dot{D}_i \sigma_i - \left( Y_{di} + Y_{Ti} + \zeta_{0} \right) \sigma_i \left| - K_f \sigma_i^2 - T_i D_i^{-1} \Gamma \sigma_i \right| \leq |D_i| \left| \sigma_i \right| - Y_{di} |\sigma_i| - T_i D_i^{-1} \Gamma |\sigma_i| - \zeta_{0} |\sigma_i| - K_f \sigma_i^2 \quad (97)
\]

\[
\left| \sigma_i \right| \leq \left| \sigma_i \right| \left( 1 + T_i D_i^{-1} \Gamma \right) \leq \left| \sigma_i \right| \left( 1 + \frac{T_i \Gamma}{D_i} \right) \leq \left| \sigma_i \right| \frac{T_i \Gamma}{D_i} \quad (98)
\]
According to Assumption (2) and exploiting (97), one has
\[
\dot{Y}_g = \sigma_x \dot{\sigma}_x + \sigma_y \dot{\sigma}_y + \sigma_z \dot{\sigma}_z + \sigma_\phi \dot{\sigma}_\phi + \sigma_\theta \dot{\sigma}_\theta + \sigma_\psi \dot{\sigma}_\psi
\]  
\[\leq -\left( \sum_{i=x,y,z,\phi,\theta,\psi} \varsigma_{0i} |\sigma_i| + K_f \sigma_i^2 \right) < 0.\]  
(99) (100)

From (99), we can conclude that the finite-time stability is established for the quadrotor system then, the settling time satisfies
\[t_{GC} \leq t_{xc} + t_{yc} + t_{zc} + t_{\phi c} + t_{\theta c} + t_{\psi c}.\]  
Furthermore, it has been verified that the sliding variable \(\sigma_i = 0\) and then the tracking error \(e_i\) will converge to zero along the sliding surfaces at 0 and \(S_i\) successively in the finite time under the times \(t_{ix}\) and \(t_{isc}\). This one is based on the results of Theorem 2. However, the quadrotor system has six settling times one, i.e. \(t_{GC} \leq t_{xs} + t_{ys} + t_{zs} + t_{\phi s} + t_{\theta s} + t_{\psi s}\). As well as the quadrotor system trajectories will converge to zero in FnT. Finally, we demonstrate the finite-time stability of the quadrotor system and convergence time of its system, also the global setting time satisfies
\[T_{GFnT} \leq T_{xFnT} + T_{yFnT} + T_{zFnT} + T_{\phi FnT} + T_{\theta FnT} + T_{\psi FnT}.\]

5 | SIMULATION RESULTS

In this section, realistic simulation results are illustrated to assess the proposed control approach, even in comparison with the control law proposed in [12].

Remark 5. The smoothness of thrust and torques of the vehicle, external disturbances and other factors can really have an impact on the position and attitude desired control performances. To strike a balance between the trade-offs of control precision, energy consumption, and signal smoothness, suitable values for the control parameters should be chosen. Due to these factors, Simulation 1 (without disturbances) uses the toolbox of optimization in the MATLAB software to choose the optimal values for the controller parameters, and the remaining scenarios use the same parameters (see Ref. [47]).

From (15), the parameters of \(\Lambda\) and \(\alpha\) in (15) directly influence on the control performance. \(t_f\) is more sensitive to of the parameter \(\Lambda\) than to \(\alpha\) variations in the parameter.

5.1 | Settings

In the following a wide simulation campaign is discussed. More specifically, the following scenarios are considered:

Nominal model: In this scenario the proposed FORITSM control for position tracking is considered by using nominal parameters of the quadrotor. In addition, the simulation results of the proposed controller are compared with those achieve by using the control law in [12].

Increasing disturbance amplitudes: In this scenario the proposed controller and the controller proposed in [12] are tested considering the disturbances in (101) and (102) applied respectively for position and attitude of the quadrotor, by increasing their amplitudes with respect to time:

\[
D_x = \sin(4t) + \cos(4t), \ t \in [0, \pi]
\]
\[
D_x = 1.3 \sin(4t) + 1.3 \cos(4t), \ t \in [\pi, 80]
\]
\[
D_y = \sin(5t) + \cos(5t), \ t \in [0, \frac{5}{7}\pi]
\]
\[
D_y = 1.1 \sin(5t) + 1.4 \cos(5t), \ t \in \left[\frac{2}{7}\pi, 80\right]
\]
\[
D_z = \sin(5t) + \cos(5t), \ t \in [0, 2\pi]
\]
\[
D_z = 2 \sin(4t) + 2 \cos(5t), \ t \in [2\pi, 80]
\]

(101)
and

\[ D_\phi = 1.3 \sin(5t) + 1.3 \cos(5t), \quad t \in [0, 2\pi] \]
\[ D_\phi = 4 \sin((5t) + 4 \cos(5t), \quad t \in [0, 2\pi] \]
\[ D_\theta = 1.6 \sin(5t) + 1.6 \cos(5t), \quad t \in [0, 2\pi] \]
\[ D_\theta = 4 \sin(5t) + 4 \cos(5t), \quad t \in [2\pi, 80] \]
\[ D_\psi = 1.5 \sin(5t) + 2 \cos(5t), \quad t \in [0, 2\pi] \]
\[ D_\psi = 5 \sin(4t) + 5 \cos(5t), \quad t \in [2\pi, 80]. \quad (102) \]

**Increasing disturbance frequencies:** In this scenario the proposed control method and the controller proposed in [12] are tested considering the disturbances in (103) and (104) applied respectively for position and attitude of the quadrotor, by increasing their frequencies with respect to time.

\[ D_x = \sin(4t) + \cos(4t), \quad t \in [0, \pi] \]
\[ D_x = \sin(40t) + \cos(40t), \quad t \in [\pi, 80] \]
\[ D_y = \sin(5t) + \cos(5t), \quad t \in [0, \frac{5}{7}\pi] \]
\[ D_y = \sin(50t) + \cos(50t), \quad t \in [\frac{5}{7}\pi, 80] \]
\[ D_z = \sin(5t) + \cos(5t), \quad t \in [0, 2\pi] \]
\[ D_z = \sin(100t) + \cos(100t), \quad t \in [2\pi, 80] \]

and

\[ D_\phi = 3 \sin(5t) + 3 \cos(5t), \quad t \in [0, 2\pi] \]
\[ D_\phi = \sin((100t) + \cos(100t), \quad t \in [2\pi, 80] \]
\[ D_\theta = 1.6 \sin(5t) + 1.6 \cos(5t), \quad t \in [0, 2\pi] \]
\[ D_\theta = 1.6 \sin(5t) + 1.6 \cos(5t), \quad t \in [2\pi, 80] \]
\[ D_\psi = 5 \sin(100t) + 2 \cos(100t), \quad t \in [0, 2\pi] \]
\[ D_\psi = \sin(100t) + \cos(100t), \quad t \in [2\pi, 80] \]

The quadrotor parameters for the considered scenarios are reported in Table 1, while the control parameters are given by \(\mu_1 = \frac{9}{16}, \mu_2 = \frac{9}{23}, \alpha_1 = 0.2, \beta_{12} = 72, \Lambda_1 = 0.05, \epsilon_0 = 0.5, \kappa_2 = 72, \kappa_1 = 192, \gamma_{di} = 14, \) and \(\gamma_{Ti} = 2.4.\)
5.2 Nominal model

Now the first scenario in nominal conditions is discussed. Fig. 3 shows the reference position tracking results. It can be observed that, by using the proposed method, fast and precise trajectory tracking is achieved, differently from the case when the method proposed in [12] is adopted. Indeed, the latter determines a big overshoot in the position outputs. The tracking performance of the attitude is instead plotted in Fig. 4 with satisfactory results when using the proposal. The tracking errors including \( e_x \), \( e_y \), \( e_z \), and \( e_{\psi} \) are zeroed as expected and displayed in Fig. 5. The results of the tracking in 2D and 3D environments are plotted respectively in Fig. 6 and Fig. 7. Fig. 8 finally shows the results of the control inputs whose amplitudes are small and converge to their nominal values. The input results of both proposed controller and the controller proposed in [12] are similar in this case. Moreover, the next scenario we increasing disturbance amplitudes in the quadrotor system.

![Simulation results showing the position performance of each controller: reference ( ), control in Feng et al. (2014) ( ), and proposed method ( ) (Nominal model).](image)

5.3 Increasing disturbance amplitudes

To show the improvement obtained by the proposed controller, a comparative study with three nonlinear controllers is considered in this case. The existing controllers are proposed by the authors Feng et al. [12], Shi et al. (2019) [48], and Labbadi et al. [49]. The results of the second scenario are now discussed with other three controllers. It can be seen that the proposed controller drives the outputs to converge to their desired trajectories in FnT. Moreover, the negative effect caused by the presence of the disturbances is removed. On the other hand, it can be noticed that the results provided by the control laws in [12], [48], and [49] are less satisfactory than the ones achieved via the proposed method, see, for example, Fig. 9 where high oscillation are present. The attitude and tracking errors are plotted respectively in Fig. 10 and 11. Again, it can be observed that the attitude and tracking errors are zeroed. Finally, Figs. 12 and 13 of three controllers show that the proposed controller allows to achieve a good tracking performance compared to [12], [48], and [49]. The amplitudes of the inputs presented in Fig. 14 are small and with a reduced chattering phenomenon of both proposed controller and the approach proposed in [12]. Indeed, the input results [48] and [49] are not small and with high amplitudes.
5.4 Increasing disturbance frequencies

The results of the third scenario are illustrated hereafter. In terms of the convergence rate, rejection of the disturbances, and tracking performance, the proposed controller outperforms the one in [14] as shown in Figs. 15 and 16 for position and attitude respectively, as well as in terms of tracking errors. In fact, the proposed approach ensures fast convergence rate with lower undershoot of the system-controlled outputs. Indeed, the tracking performance of the 2D and 3D trajectories are displayed in Figs. 18 and 19. On the other hand, the proposed method generates continuous control signals as displayed in Fig. 20, which reduces chattering and improves the closed-loop system tracking control performance.

Remark 6. The results in Fig. 20 demonstrate that the type of disturbances that can impact the quadrotor system determines the algorithm that gives a lower upper bound of switching controller, as a result, a lower chattering amplitude. This is because this technique addresses the disturbance directly, but the proposed strategy addresses the disturbance’s derivative.

Remark 7. The proposed controller has two parts. The first part is based on two layers of sliding mode variables with one FO operator. The second term of the proposed controller is based on FO switching controller. This makes the proposed controller more robust against the change of the frequencies of the disturbances due to the use of fractional-order operators in its design. In another hand, the proposed controller used switching gains to make it more robust against the change of the amplitude disturbances.

5.5 Quantitative analysis of the controllers

This section will qualitatively assess the benefit of the proposed controller in reducing the impact of the rate limit. The closed-loop system, which exhibits system stability, has a potential for infinite loops, which are the main focus of the analysis. For quantitative comparison, the integral of the square value of the error (ISE), \( \int_b^t e^2 dt \), is utilized. A numerical illustration of tracking-error performance is the ISE. For situations 2 “Increasing disturbance amplitudes”, the ISE performance of four controllers is displayed in Table 2. The proposed control strategy demonstrates that the ISE indices are less significant than the
controllers proposed Feng et al. (2014)\cite{feng2014}, Shi et al. (2019)\cite{shi2019}, and Labbadi et al. (2020)\cite{labbadi2020}. According to the quantitative analysis in Table\ref{tab:ISE}, the suggested control results in decreased ISE error values for the quadrotor’s position and orientation. The ISE values for the tracking errors are reduced when compared to the outcomes of the other procedures. These results all point to the suggested control method’s ability to improve tracking performance in terms of high tracking precision, rapid reaction, fluid control commands, and high resilience. This study’s control strategy has higher tracking control performance, which has been demonstrated. In terms of tracking precision, convergence speed, and resilience against disturbances, it performs better than other approaches. On the other hand, the integral absolute derivative control signal (IADU) index has been calculated for all control signals in the scenario 2. The smoothness of control signals can be easily determined using this performance metric. As shown in Table\ref{tab:IADU}, the proposed method produces smoother input control signals than the alternative strategy, indicating the effectiveness of the proposed controller. The simulation’s results are displayed in Table\ref{tab:simulation}. It can be seen that the proposed control approach for all control signals enhances smoothness. Comparing the proposed control to the \cite{feng2014,shi2019,labbadi2020} techniques in

Table 3 it can be shown that the suggested control can ensure the least amount of transmission data controller-to-motor ends, considerably cutting consumption energy and lowering unnecessary expenditures.

6  |  CONCLUSIONS

This paper proposed a FO command filtered-based recursive finite-time control using a nonsingular terminal sliding mode technique for high-order uncertain nonlinear systems under disturbances with unknown bounds. The proposed control is developed to get beyond the limitations of existing finite-time tracking controllers like the TSM control. Furthermore, in the proposed approach, the reaching phase is removed, the explosion of complexity in the control problem is avoided, and a chattering alleviation property is achieved. Then, this fractional-order strategy has been applied to control a quadrotor UAV system in different scenarios affected by increasing disturbance amplitudes and frequencies. This technique has been proved to be an appropriate

solution for controlling such systems and ensuring the needed tracking. Furthermore, simulation results have demonstrated the effectiveness of the proposal even in comparison with an existing approach in the literature.

As future work, we consider the situation where observers, controllers, and consensus algorithms all meet finite-time performance goals. Future research will focus on the proposed controller’s adaptive mechanism. Future consideration will also be given to the extension to the examination of high-order systems’ fixed-time stability.
